PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized complilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism, and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

Use of Funds for Printing this publication
approved by the Director of the Bureau of
the Budget on April 30, 1972.

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

554 CYTOCHEMISTRY OF GOLGI FRACTIONS PREPARED
FROM RAT LIVER. *(E.)* Farquhar, M. G.;
ergeron, J. J. M.; Palade, G. E. (Yale Univ. Sch.
f Med., New Haven, Connecticut). *J. Cell Biol.*
)(1):8-25, 1974.

ytochemical tests for several marker enzymes were
pplied to liver tissue and to the three Golgi frac-
ions (GF_1, GF_2, GF_3) separated by the procedure
f Ehrenreich et al. from liver homogenates of alco-
ol treated male Sprague-Dawley rats. 5'-Nucleoti-
ase (AMPase) reaction product was found in all
hree fractions but in different locations: It oc-
urred along the inside of the membrane of VLDL-
illed vacuoles in GF_1 and GF_2, and along the out-
ide of the cisternal membranes in GF_3. In the latter
t was restricted to the dilated cisternal rims and
as absent from the cisternal centers. The AMPase
ctivity found in the fractions by biochemical as-
ay is therefore indigenous to Golgi components and
s not due to contamination by plasma membrane. Acid
hosphatase (AcPase) reaction product was detected
ithin lysosomal contaminants in GF_1 and within many
LDL-filled vacuoles in GF_1 and GF_2, indicating that
cPase activity is due not only to contaminating
ysosomes, but also to enzyme indigenous to Golgi
ecretory vacuoles. G-6-Pase reaction product was
resent in GF_3 and within contaminating endoplasmic
eticulum fragments, but not in other fractions.
hiamine pyrophosphatase (TPPase) was localized to
ome of the VLDL-filled vacuoles and cisternae in
F_1 and GF_2, and was not found in the cisternae in
F_3. The results demonstrate the usefulness of cyto-
hemical methods in monitoring the fractionation
rocedure: They have (*a*) allowed a reliable identi-
ication of contaminants, (*b*) made possible a dis-
inction between indigenous and contaminating ac-
ivities, and (*c*) shown, primarily by the results of
he TPPase test, that the procedure achieves a mean-
ngful subfractionation of Golgi elements, with GF_1
nd GF_2, representing primarily trans-Golgi elements
rom the secretory Golgi face, and GF_3 consisting
argely of cis-Golgi components from the opposite
ace.

55 GALLBLADDER AND BILE DUCT ULTRASTRUCTURE.
IV. CHOLESTEROSIS OF THE HUMAN GALLBLADDER
JCOSA. *(Ger.)* Luciano, L.; Wolpers, C. (Med. Coll.,
annover, Germany). *Virchows Arch (Zellpathol.)*
(2):147-158, 1973.

trastructural examinations were made of chief cells
the epithelium and connective tissue cells in the
amina propria of gallbladders removed from 3 fe-
ale patients, aged 28, 44, and 68 yr. A well-de-
eloped smooth endoplasmic reticulum was found in
he chief cells of the epithelium. Many macropha-
es were found between the epithelial cells and in
he lamina propria, and some of these macrophages
ere entering or leaving the basement membrane.
ome of the intraepithelial macrophages contained
lattened, smooth-surfaced cisternae connected
ith the rough endoplasmic reticulum. These smooth-
irfaced cisternae were more numerous and larger
in other macrophages located next to the epithelium in the lamina propria. As the distance from the epithelium increased, these structures became larger and finally resembled foam cell vacuoles, but freeze-etching showed that they contained lipids. The highly developed smooth endoplasmic reticulum in both epithelial cells and macrophages suggests that this structure is involved in lipid transport or deposition. Morphological differences between the "vacuoles" might be due to differences in their lipid content or to temperature differences which aid in the solution of this problem.

2556 STRUCTURAL DIFFERENCE BETWEEN LUMINAL AND LATERAL PLASMALEMMA IN PANCREATIC ACINAR CELLS. *(E.)* DeCamilli, P.; Peluchetti, D.; Meldolesi, J. (Dept. Pharmacol., Univ. Milan, Italy). *Nature* 248(5445):245-247, 1974.

Small pancreas tissue fragments from male albino guinea pigs were freeze-fractured. Large areas of both the luminal and lateral plasmalemma were exposed by cleavage. After cleavage, most of the particles are associated with the half of the membrane left frozen to the cytoplasm (the A face). The face of the half membrane left frozen to the extracellular space (the B face) bears fewer particles/unit area. In pancreatic acinar cells, the typical A face pattern can be found only in the basal and lateral portions of the plasmalemma (including the regions close to the tight junctions and within the chambers delimited by their network). Over the entire luminal area, there are far fewer particles/unit area of the A face. The transition is very sharp across the inner continuous line of the tight junction delimiting the lumen. On the B face the number of particles is always very small, with no clear difference between the luminal and the lateral portions of the plasmalemma. The limiting membranes of the zymogen granule stored within the cells bear many fewer particles/unit area than the membranes of the other cytoplasmic organelles. The distribution is again asymmetrical with more particles in the A face than in the B face. It is suggested that the zymogen granule membranes and the luminal portion of the plasmalemma might be part of a unique pool of membranes which are continuously shuttled backward and forward between the newly formed zymogen granule and the luminal surface.

2557 ON THE SPATIAL ARRANGEMENT OF PROTEINS IN MICROSOMAL MEMBRANES FROM RAT LIVER. *(E.)* Kreibich, G.; Hubbard, A. L.; Sabatini, D. D. (New York Univ. Sch. Med., N.Y.). *J. Cell Biol.* 60(3): 616-627, 1974.

Rat liver rough microsomes were labeled enzymatically with ^{125}I using lactoperoxidase and glucose oxidase. In intact microsomes only proteins exposed on the outside face of the microsomal membrane were iodinated. Low concentrations of detergent (0.049% deoxycholate) were used to allow entrance of the iodination system into the vesicles without disassembling the membranes. This led to iodination of the soluble content proteins and to an increased labeling of the membrane proteins. The distribution of radioactivity in microsomal proteins was analyzed after separation by sodium dodecyl sulfate acrylamide gel electrophoresis. Most membrane proteins were labeled when intact microsomes were iodinated. No major membrane proteins were exclusively labeled in the presence of low detergent concentrations or after complete membrane disassembly. Therefore, it is unlikely that any major membrane proteins, other than glycoproteins, are located exclusively on the inner membrane face or completely embedded within the microsomal membrane. Microsomal proteins were also labeled by incubating rough microsomes with (^{3}H)-NaBH$_4$ after reaction with pyridoxal phosphate. Microsomal membranes were permeable to these small molecular weight reagents as shown by the fact that proteins in the vesicular cavity as well as membrane proteins were labeled with this system.

2558 FUNCTIONAL CHARACTERISTICS OF PEYER'S PATCH LYMPHOID CELLS. I. INDUCTION OF HUMORAL ANTIBODY AND CELL-MEDIATED ALLOGRAFT REACTIONS.

(E.) Kagnoff, M. F.; Campbell, S. (Dept. Med., Univ. California, San Diego). *J. Exp. Med.* 139(2):398-406, 1974.

Peyer's patches from normal mice (C57BL/6 or BALB/c) contain antigen-sensitive B and T cells, but lack the accessory adherent cell type(s) required both for the induction of humoral immune responses and for the induction of allograft reactions against cell surface alloantigens. Immune responsiveness can be restored to cultures of Peyer's patch cells by the addition of either adherent peritoneal exudate cells or 2-mercaptoethanol. Peyer's patch B cells can be specifically induced by antigen to synthesize humoral antibody. Peyer's patch T cells can cooperate in B-cell induction and can be induced to mediate an allograft reaction against an allogeneic stimulus. The allograft response is prevented when T cells are removed by antitheta serum produced in AKR/J mice by i.v. injections of C3HeB/FeJ thymus cells. In normal mice Peyer's patch lymphoid aggregates appear to be a storehouse of antigen-sensitive cells sequestered in such a way as to lack an accessory cell type or factor required for induction.

2559 MEMBRANE GLYCOPROTEINS OF THE RAT SMALL INTESTINE CHEMICAL COMPOSITION OF MEMBRANE GLYCOPROTEINS.

(E.) Kim, Y. S.; Perdomo, J. M. (Univ. California Sch. Med., San Francisco). *Biochim. Biophys. Acta* 32(1):111-124, 1974.

The glycoprotein and glycolipid content of brush border and submicrosomal membranes from the mucosa of the small intestine was investigated in male Sprague-Dawley rats. The microsomal preparations were treated to remove the "non-membranous" material before analysis. In all of the membranes nearly 80% of the carbohydrate was associated with the protein fraction, and 20% with the lipid fraction. The carbohydrate of the protein fraction consisted mainly of mannose, galactose, glucose, fucose, glucosamine, and galactosamine. With the exception of ribose, which was found only in the rough microsomal membrane, all the other sugars were present in similar quantities in all the membranes. The sugars in the lipid portion of the membranes consisted primarily of galactose and glucose. Amino sugars associated with the lipid fraction were found in the brush border membrane but were nearly absent in the internal membranes. Sialic acid was low in the protein and lipid fractions of all membranes. When sodium dodecylsulfate-gel electrophoresis of the membrane protein fractions was performed, many protein and glycoprotein bands were revealed. Each membrane had a different electrophoretic pattern both with respect to protein and to glycoprotein. The data obtained from this study suggest that internal membranes as well as the brush border membranes of the intestinal cells contain glycoproteins and glycolipids.

2560 HYPERPLASIA OF THE GASTRIC GLANDS AFTER SMALL BOWEL RESECTION IN THE RAT.

(E.) Winborn, W. B.; Seelig, Jr., L. L.; Nakayama, H.; Weser, E. (Univ. Texas Med. Sch., San Antonio). *Gastroenterology* 66(3):384-395, 1974.

One month and 7 months after proximal or distal small bowel resection, the number of epithelial cell of the gastric glands increased significantly in adult Sprague-Dawley rats. After 7 months, the increase in total gastric epithelial cells was significantly greater after proximal than after distal resection. There was no difference in cell counts 1 and 7 months after distal resection. At both 1 and 7 months after proximal or distal resection, there were no significant changes in the percentage of parietal cells. Light- and electron-microscopic studies indicate that the new parietal cells differentiate from mucous cells located in the isthmus of the gastric glands. This process of maturation of the parietal cells of the gastric glands is reminiscent of the differentiation observed in later embryo ic life and in transplanted gastric mucosa.

2561 ULTRASTRUCTURE OF HEPATOMA CELLS DETECTED IN PERITONEAL FLUID.

(E.) Woyke, S.; Domagala, W.; Olszowski, W. (Med. Acad., Szczecin, Poland). *Acta Cytol. (Baltimore)* 18(2):130-136, 1974.

The ultrastructural features of hepatoma cells detected in peritoneal effusion of a 24-yr-old woman were studied. Numerous mitochondria, large Golgi complexes, and dense bile-like material in the cytoplasm as well as the formation of bile canaliculi between adjacent hepatoma cells were characteristic ultrastructural features of hepatoma cells. Electron microscopic examination may be helpful in differentiating hepatoma cells from cells of other mali nant tumors encountered in effusions.

2562 DYNAMICS OF CYTOPLASMIC MEMBRANES IN GUIN PIG PANCREATIC ACINAR CELLS. I. SYNTHESI AND TURNOVER OF MEMBRANE PROTEINS.

(E.) Meldolesi J. (Dept. Pharmacol., Univ. Milan, Italy). *J. Cell Biol.* 61(1):1-13, 1974.

e rate of synthesis and the turnover of cytoplasmic
mbrane proteins were determined in the acinar cells
guinea pig pancreas with the aim of investigating
e mechanisms by which the intracellular transport
secretion products occurs. These cells are highly
ecialized toward protein secretion. *In vitro*
lse-chase experiments and *in vivo* double-labeling
periments, using radioactive L-leucine as the
acer, revealed that the turnover of secretory pro-
ins is much faster than that of all membranes in-
lved in their transport (rough and smooth microsome
d zymogen granule membranes). Sodium dodecyl
lfate-polyacrylamide disk gel electrophoresis of
mbrane proteins revealed that in each of these mem-
anes there is a marked heterogeneity of turnover;
nerally the high molecular weight polypeptides have
shorter half-life than the low molecular weight
lypeptides. These data indicate that the membranes
rticipating in the intracellular transport of se-
etory proteins are not synthesized concomitantly
th the latter. Rather, they are probably reutilized
several successive secretory cycles. It is con-
uded that it would be desirable to study other cell
stems in a carefully controlled manner, in order to
tablish the generality of the findings on pancreatic
inar cells.

63 KUPFFER CELL REACTIONS IN RAT LIVER
UNDER VARIOUS CONDITIONS AS OBSERVED IN
E ELECTRON MICROSCOPE. *(E.)* Wisse, E. (Lab.
ectron Microscopy, Univ. Leiden, Netherlands).
Ultrastruct. Res. 46(3):499-520, 1974.

pffer cell fine structure was studied in Wistar
ts after Thorotrast administration (3.0 ml/kg
v.), splenectomy, reticuloendothelial system sti-
lation with zymosan (a single i.v. injection of
mg or 5 daily injections of 4 mg/100 g), bile
ct ligation, and partial hepatectomy. In addi-
on, Kupffer cell morphology in Gunn rat livers
s examined. Ten min after Thorotrast injection,
merous thrombocytes were observed in the vicinity
endocytosing Kupffer cells. After 30 min large,
gregated masses of Thorotrast particles surround-
g chylomicrons were present on the Kupffer cell
rface. The chylomicrons phagocytosed at 3 hr,
en degranulation of Thorotrast-containing neutro-
ils was observed. After 2 days newly formed
nse bodies contained less Thorotrast. Worm-like
ructures and bristle-coated micropinocytotic
sicles played only a minor role in endocytosis.
anuloma formation was observed after Thorotrast
d zymosan injection. While other cell types took
small amounts of Thorotrast, zymosan particles
re taken up exclusively by Kupffer cells. No
anges in Kupffer cell morphology were found in
nn rats, and in Wistar rats there were only minor
anges after zymosan, splenectomy, bile duct liga-
on, and partial hepatectomy. Kupffer cell mitosis
curred after Thorotrast, zymosan, and partial
patectomy. This phenomenon contradicts the
pothesis that Kupffer cells derive from other
lls, including endothelial cells and monocytes.
nocytes and Kupffer cells differ with respect to
agocytic capacity, morphology, origin, and cyto-
emistry. The evidence favors the independent,
lf-proliferating activity of Kupffer cells.

2564 CHARACTERIZATION OF GASTRIC MUCOSAL MEMBRANES. VI. THE PRESENCE OF CHANNEL-FORMING SUBSTANCES. *(E.)* Sachs, G.; Spenney, J. G.; Saccomani, G.; Goodall, M. C. (Dept. Gastroenterol., Univ. Alabama, Birmingham). *Biochim. Biophys. Acta* 332(2):233-247, 1974.

Highly purified gastric membranes were extracted by ionic or nonionic detergents. Further fractionation was carried out on acrylamide gel electrophoresis. Some defined bands, incorporated into artificial bilayer membranes, produced discrete conductance changes characteristic of channel activity. A low molecular weight peak, purified through 2 cycles of electrophoresis, was characterized as an anion-selective, positively voltage dependent channel. A function for this channel in transport ATPase is postulated. The enzyme is visualized as an electrogenic pump, responsible for increased $OH^-(HCO_3^-)$ translocation. The anion channel is the parallel limb of the circuit, and being voltage dependent, would transport Cl^- in response to ATPase activity. The net result would be HCL secretion, and intracellular production of HCO_3^-, which is dissipated by a Cl^--HCO_3^- forced exchanged mechanism in the basal membrane.

2565 THE INFLUENCE OF ADRENORECEPTOR ACTIVITY ON CRYPT CELL PROLIFERATION IN THE RAT JEJUNUM. *(E.)* Tutton, P. J. M.; Helm, R. D. (Dept. Anat., Monash Univ., Clayton, Victoria, Australia). *Cell Tissue Kinet.* 7(2):125-136, 1974.

The influence of adrenergic stimulation, adrenergic blockade, and sympathectomy on crypt cell cycle time and mitotic time in male rat jejunum was studied. Alpha adrenergic stimulation by norepinephrine (1 μg/kg/min i.v.) shortened both cell cycle and mitotic times, whereas beta adrenergic stimulation by epinephrine (10 μg/kg/min i.v.) or isoproterenol (5 μg/kg/min i.v.) prolonged both cell cycle and mitotic times. Conversely, alpha adrenergic blockade by phentolamine (10 mg/kg i.p.) prolonged cell cycle time and beta adrenergic blockade by propranolol or practolol (each 10 mg/kg i.p.) shortened cell cycle time but not mitotic time. Both chemical and surgical sympathectomy inhibited crypt cell proliferation. Chemically sympathectomized animals manifested supersensitivity to exogenous norepinephrine. These results suggest the presence of an alpha adrenoreceptor within the intestine which is capable of stimulating cell division.

2566 RAPID RADIATION CELL DEATH AND CELL PROLIFERATION IN INTESTINAL EPITHELIUM AFTER 1000-RAD IRRADIATION. *(E.)* Tsubouchi, S.; Matsuzawa, T. (Aichi Cancer Ctr. Res. Inst., Nagoya, Japan). *Radiat. Res.* 57(3):451-458, 1974.

Rapid cell death of female lCR/JCL mouse intestinal crypt cells was investigated after 1000 rads of x-irradiation by counting pyknotic cells in tissue sections. The number of normal crypt cells decreased with the appearance of pyknotic cells after irradiation. Pyknotic cells appeared within 30 min and the number of pyknotic cells reached a maximum 4 hr after irradiation. From the disappearance rate of the cells the mean life span of pyknotic cells was estimated to be 2 hr or less. Pyknotic cells observed within 4 hr after irradiation were produced without cell division, and this interphase death by pyknosis occurred in all phases of cell cycle. The tendency for the cells to develop into pyknotic cells was high in G2 phase, intermediate in S phase, and low in G1 phase. The increase in mitotic index and the decrease in pyknotic cells from the 2nd to the 5th day after irradiation were inversely related. After the disappearance of pyknotic cells, rapid recovery of the cell population took place with logarithmic cell proliferation and shortening of the cell cycle. Recovery to the normal cell population level was attained within 5 days after irradiation.

2567 THE ENDOCRINE CELLS OF THE UPPER GUT MUCOSA IN DOGS WITH TRANSPLANTATION OF THE PYLORIC ANTRUM TO THE COLON. *(E.)* Lechago, J.; Bencosme, S. A. (Dept. Path., Queen's Univ., Kingston, Canada). *Z. Zellforsch.* 146(2):237-242, 1973.

An antrum transplantation to the colon was performed in 6 dogs of both sexes. Four of these animals developed gastric juice hypersecretion around the 12th postoperative day, while the 2 remaining dogs showed no changes in gastric juice output for as long as 3 months following surgery. The tissues from the transplanted antrums of the first 4 dogs showed a marked increase in enterochromaffin (EC) cells under light microscopy. Under light microscopy, the antral G or gastrin cells showed no obvious changes in number or appearance, although electron microscopic examination revealed slight ultrastructural changes in these cells. No ultrastructural changes were observed in the EC cells. There were no changes in the endocrine cells of the other areas of the upper gut. The mucosal tissues of the dogs which did not develop gastric hypersecretion were essentially indistinguishable from those of normal dogs. The EC cell hyperplasia may be related to the EC hyperplasia reported in the stomachs of some human patients with gastric hypersecretion and peptic ulcer. It is possible that some biogenic amines stored in the enterochromaffin cells of the stomach may have an acid secretogogue function.

2568 ULTRAHISTOCHEMICAL DETECTION OF BIOGENIC AMINES WITH REINECKE SALT IN GUINEA-PIG (Cavia cobaya) PANCREAS. *(Ger.)* Hahn von Dorsche, H.; Krause, R. (Anat. Inst., Ernst Moritz Arndt Univ., Greifswald, Germany). *Z. Mikrosc. Anat. Forsch.* 87(2):287-292, 1973.

The tail of the pancreas was removed from fasted adult male guinea pigs and placed in a buffered Reinecke salt solution (2:5 dilution) before treatment with osmium tetroxide. Examination of ultrathin sections under the electron microscope revealed the presence of vesicles in cells of the exocrine pancreas. These vesicles had an average diameter of 500 μm and all of them were bounded by a clearly defined membrane. Although some of these vesicles were empty, most contained material which was precipitated by Reinecke salt. Nuclei and a reduced number of mitochondria were present in cells containing these vesicles, but no evidence of archoplasm or the Golgi apparatus was detected. Other cells contained both these vesicles and zymogen granules, but the density of vesicles in these cells was lower than in cells which did not contain zymogen granules. Since Reinecke salt is a specific precipitator of amines, the vesicles must contain amines, but no information is available about their composition. Since vesicle-containing cells were scattered throughout the pancreas, it is suggested that amine-producing cells regulate the activity of parenchymal cells in the pancreas.

2569 NEUROHISTOCHEMICAL CHANGES IN THE WALL OF THE GALL-BLADDER INJURED BY THE LIGATION OF THE COMMON BILE DUCT. *(E.)* Ungvary, Gy.; Donath, T.; Naszaly, S. A. (Semmelweis Med. Univ., Budapest, Hungary). *Acta Morphol. Acad. Sci. Hung.* 21(3):281-293, 1973.

The common bile ducts of 56 guinea pigs were ligated near Vater's ampulla in an operation which left the nerves of the gall bladder uninjured. Although there was some damage to the enzyme systems (succinate dehydrogenase, nonspecific esterase, alkaline phosphatase) which characterize function in the normal gall bladder, the organ was still considered living in that these enzymes were functioning up to 1 week after the ligation. Within 24 to 48 hr, the "intact" neurons of the gall bladder had lost their catecholamine storage and/or uptake capacity. One day after the intervention, neurohistochemical means did not reveal functioning of the monoaminergic nerves, while after 2 days, functioning of the acetylcholinesterase-positive and zinc-iodine-osmium positive nerves was not demonstrable. While these phenomena do not necessarily indicate a functional loss in these nerves, they do suggest that significant changes occurred in the innervation of the gall bladder. Using silver impregnation techniques, the presence of nerve fibers in the gall bladders of the operated animals was demonstrated up to 1 week after the innervation.

2570 BIOCHEMICAL AND ULTRASTRUCTURAL STUDY OF GLYCOGEN IN JEJUNAL MUCOSA OF DIABETIC RATS (37790). *(E.)* Anderson, J. W.; Jones, A. L. (Veterans Administration Hosp., San Francisco, Calif.). *Proc. Soc. Exp. Biol. Med.* 145(1):268-272, 1974.

The glycogen concentration of jejunal mucosa was 423 μg/g or 0.04% of wet weight in normal rats. Diabetes was accompanied by a twofold increase in glycogen content whereas a 72-hr fast produced a 50% reduction of gut glycogen. In absorptive cells of diabetic rats β glycogen was observed throughout the cytoplasm but appeared particularly abundant in the terminal web region. The adaptive responses of gut glycogen levels to fasting and refeeding were similar to changes in the activities of gut glycolytic enzymes but glycogen and enzyme changes were less marked than those observed for the liver of the same animals.

'571 SCANNING AND TRANSMISSION ELECTRON MICROSCOPIC STUDIES OF JEJUNAL MICROVILLI OF THE AT, HAMSTER, AND DOG. *(E.)* Anderson, J. H.; Tayor, A. B. (Univ. of Illinois, Urbana). *J. Morphol.* 41(3):281-292, 1974.

canning and transmission electron microscopy were sed to investigate the surface area and number per nit area of microvilli from jejunal villus epithelal cells in the rat, hamster and dog. The calculated ean microvillus surface area was 0.419 μ^2, 0.573 μ^2, .751 μ^2 for the rat, hamster and dog respectively. he largest number of microvilli per square micron reeze dried villus surface was measured in the rat ith a mean value of 65. Hamster and dog freeze ried specimens had lower mean values of 54 and 34 icrovilli respectively. The total microvilli surace area in square micron per square micron villus urface was more closely related for the three pecies with values of 27.23 for the rat, 30.94 for he hamster and 25.53 for the dog. These data indiate an inverse relationship between the mean microillus surface area and population density in the pecies studied. However, the total microvilli urface area per unit villus surface is relatively imilar for the three species. The observed number f microvilli per unit villus surface varied depening upon the dehydration technique employed for reparation of scanning electron microscopic speciens. This variation probably reflects shrinkage rtifact and should be considered in soft tissue tudies involving the scanning electron microscope.

572 EPITHELIAL CELL SPECIALIZATION WITHIN HUMAN PEYER'S PATCHES: AN ULTRASTRUCTURAL TUDY OF INTESTINAL LYMPHOID FOLLICLES. *(E.)* Owen, . L.; Jones, A. L. (Veterans Administration Hosp., an Francisco, Calif.). *Gastroenterology* 66(2): 89-203, 1974.

he "M"(microfold) cell, a previously unrecognized uman intestinal mucosal cell type, is described rom studies by light microscopy, transmission elecron microscopy, and scanning electron microscopy. cells, characterized by luminal surface microfolds ather than microvilli, are located in areas of oncolumnar epithelium overlying lymphoid follicles n Peyer's patches. Attenuated M cell processes form latticework, allowing lymphoid cells to approach o within 0.3 μm of the intestinal lumen while mainaining the integrity of the intestinal epithelium. hese newly discovered epithelial cells contain muliple vesicles that suggest a transport function, ossibly for luminal antigenic material or for secreory immunoglobulin. Neither the transported comonents nor the direction in which transportation ccurs is known. However, at least two possibilities re worth investigation: 1) the lymphoid cells conained within M cell pockets could be responding here to antigenic material transported from the ntestinal lumen via the M cells, or 2) M cells may ouple IgA to secretory component and transport the mmunoglobulin complex into the lumen. Both suggestons are compatible with the observations.

573 SMALL INTESTINAL DAMAGE AND CHANGES IN CELL POPULATION PRODUCED BY ETHANOL INGESTION IN THE RAT. *(E.)* Baraona, E.; Pirola, R.; Lieber, C. S. (Veterans Administration Hosp., Bronx, N.Y.). *Gastroenterology* 66(2):226-234, 1974.

Acute intragastric administration of ethanol in concentrations similar to those of common alcoholic beverages produced hemorrhagic erosions of the small intestinal villi in CD rats from the Charles River Breeding Laboratories. The lesions were most obvious proximally and were concentration-dependent. Moderate lesions produced by a low ethanol concentration (5 g per 100 ml) were associated with decreased activities of jejunal lactase (-25%), and thymidine kinase (-18%), and a reduced O_2 consumption of jejunal slices (-25%). Chronic ingestion of ethanol in a liquid diet (5 g per 100 ml) did not produce hemorrhagic erosions. However, when compared with control rats which were pair-fed isocaloric carbohydrate for 3 to 4 weeks, alcohol-fed rats had intestinal villus changes, particularly in the jejunum, where the villi were shorter with fewer cells (-24%) and had decreased activities of jejunal lactase, sucrase, and alkaline phosphatase (-50%, -30%, -60%, respectively). By contrast, crypt changes were maximal in the ileum, with increases in cell counts (+28%), mitotic index (+59%), thymidine kinase activity (+69%), and a higher incorporation of ^{3}H-thymidine into deoxyribonucleic acid (+60%). The enzyme changes were not due to differences in carbohydrate intake since similar findings were obtained when ethanol was isocalorically substituted for dietary fat. Thus, in the rat, chronic ethanol ingestion results in a population of less mature intestinal mucosal cells with altered metabolic characteristics.

2574 ELECTRON MICROSCOPIC STUDY OF MAMMALIAN LIVER WITH PERIODIC ACID METHENAMINE SILVER STAIN: BASEMENT MEMBRANE STRUCTURE AND FIBROGENESIS IN SPACE OF DISSE. *(E.)* Kawanami, O. (Nippon Med. Sch. Tokyo, Japan). *Acta Pathol. Jap.* 23(4):717-738, 1973.

ABSORPTION-EXCRETION-TRANSPORT

06 DRUG ABSORPTION IN RATS PRETREATED WITH ANTIBIOTICS. *(E.)* Walsh, C. T.; Levine, R. (Boston Univ. Med. Ctr., Mass.). *J. Pharmacol. p. Ther.* 188(2):277-286, 1974.

e effect of alterations of the bacterial population the small intestine produced by antibiotics on e absorption of pharmacologic agents was studied male Sprague-Dawley rats. After a treatment riod during which antibiotics were administered to ts in their drinking water, assays were performed measure the ileal bacterial population and the eal absorption of a series of drugs. A mean 10-day nsumption of 100 mg/kg/day of neomycin sulfate and mg/kg/day of potassium penicillin V produced a rked reduction in the counts of coliforms and proeus, enterococci, lactobacilli and anaerobic lactoacilli and streptococci. No significant differences tween control and pretreated animals were found, wever, in the absorption of tetracycline, diphenyldantoin, or benzomethamine. A regimen of lincomyn, averaging 61 mg/kg/day for 7 days, eliminated e lactobacilli population and produced overgrowths in coliforms in 2 out of 3 experiments. The ileal absorption of benzomethamine and chlorpromazine was not affected by this antibiotic pretreatment. Three regimens of tetracycline, averaging 110 mg/kg/day for 2 days, 209 mg/kg/day for 2 days, and 338 mg/kg/day for 5 days, all produced small reductions in anaerobic lactobacilli and streptococci. No differences were observed in the absorption of chlorpromazine as a result of tetracycline pretreatment. These antibiotic regimens that altered the enteric bacterial population apparently do not produce changes that are significant to the absorption process of the drugs studied.

2607 ABSORPTION OF FOLIC ACID BY EVERTED SEGMENTS OF RAT JEJUNUM. *(E.)* Blair, J. A.; Johnson, I. T.; Matty, A. J. (Dept. Chem., Univ. Aston, Birmingham, England). *J. Physiol. (Lond.)* 236(3):653-661, 1974.

The initial uptake rate of folic acid at various concentrations and incubation temperatures were studied in everted rings of Wistar rat intestine *in vitro*. Folic acid was accumulated linearly for periods of at least 30 min. The initial uptake rate reached a constant value as the concentration of folic acid in the incubation medium was increased above 5×10^{-6} M. Reducing the temperature of incubation from 37 to 27 C gave small Q_{10} values at either end of the concentration range. Transfer of folic acid into the serosal compartment of everted sacs was shown to undergo a rate reduction in the same concentration range. A mechanism for folic acid transport is suggested in which folic acid is converted to the neutral species at the mucosal surface in an acid microclimate.

2608 ACTIVE TRANSPORT OF ZINC AND IDENTIFICATION OF ZINC-BINDING PROTEIN IN RAT JEJUNAL MUCOSA.

(E.) Kowarski, S.; Blair-Stanek, C. S.; Schachter, D. (Coll. Physicians Surg., Columbia Univ., New York, N.Y.). *Am. J. Physiol.* 226(2):401-407, 1974.

Estimations of steady-state fluxes of Zn across everted segments of male Sherman albino rat jejunum *in vitro* demonstrate a net flux from the serosal surface to the mucosal surface in excess of that predicted for passive flux. This active transport against electrochemical potential gradients is abolished by 2,4-dinitrophenol (0.5 mM) plus iodoacetate (1.0 mM). The metabolic inhibitors markedly decrease both unidirectional fluxes in the steady state. Studies with everted gut sacs demonstrate that Zn flux from mucosa to serosa is greater in the rat jejunum and ileum as compared to the proximal duodenum, is dependent on ambient Na, O_2, and a metabolizable hexose, and is at least partially dependent on vitamin D. Transfer from serosa to mucosa is also dependent on ambient Na and is greater in the jejunum and ileum as compared to the proximal duodenum. A soluble Zn-binding protein has been identified in homogenates of rat jejunal mucosa. The partially purified protein has a molecular weight of approximately 10^5 and relatively little affinity for calcium.

2609 EFFECTS OF ETHANOL ON ACTIVE TRANSPORT IN THE DOG STOMACH.

(E.) Sernka, T. J.; Gilleland, C. W.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Am. J. Physiol.* 226(2):397-400, 1974.

Experiments were performed on an *in vivo* chambered dog stomach preparation to determine whether damage to the gastric mucosa with ethanol involves impaired active ion transport. When 20% ethanol in saline was placed in contact with the mucosa of the antrectomized resting stomach, the equivalent electrical resistance across the stomach wall increased. This observation is consistent with an effect on active ion transport, but not with an increase in conductance or ion permeability in the resting stomach. The much greater reduction in potential difference following topical administration of ethanol as compared with infusion of ethanol in the bloodstream also suggests an effect on ion transport at the mucosal surface. When ethanol contacted the antrectomized secreting gastric mucosa, the rate of acid secretion fell immediately, as measured by either the pH stat method or by a buffer instillation technique. Since the lumen was kept neutral throughout these experiments, it is concluded that ethanol acts initially on ion transport rather than ion permeability in the secreting stomach.

2610 EFFECT OF GLYCYLGLYCINE AND GLYCINE ON JEJUNAL ABSORPTION RATE OF L-HISTADINE IN MAN *IN VIVO*.

(E.) Cook, G. C. (Dept. Med. Univ. Zambia, Lusaka). *J. Physiol. (Lond.)* 237(1):187-194, 1974.

Using a double-lumen tube jejunal perfusion system *in vivo*, the effects of glycylglycine and glycine on the jejunal transfer rate of L-histidine were studied in a 30-cm jejunal segment, in 6 Zambian African men. Data on the effect of L-histidine on glycylgylcine transfer rate were also obtained. The solutions perfused in each subject contained L-histidine (100 mM/liter), L-histidine (100 mM/liter) and glycylglycine (50 mM/liter), glycylglycine (50 mM/liter), and L-histidine (100 mM/liter) and glycine (100 mM/liter). The presence of glycine in the perfusing fluid significantly impaired the absorption rate of L-histidine; glycylglycine had no significant effect. The presence of L-histidine in the perfusing fluid had no significant effect on the rate of glycylglycine absorption. When compared with results for glycine absorption rate in 12 Zambian African subjects in another study, the presence of L-histidine produced a significant impairment in the rate of glycine absorption. The results demonstrate a mutual inhibition between the rates of L-histidine and glycine absorption. The lack of a similar inhibition between L-histidine and glycylglycine is consistent with the concept of independent transfer mechanisms for amino acids and dipeptides in the human jejunum.

2611 EFFECT OF PROSTAGLANDIN E_1 UPON TRANSIT TIME AND NET AND UNIDIRECTIONAL MOVEMENTS OF WATER AND ELECTROLYTES IN THE HUMAN JEJUNUM.

(Fr.) Matuchansky, C.; Mary, J. Y.; Bernier, J. J. (St. Lazare Hosp., Paris, France). *Biol. Gastroenterol. (Paris)* 5(3):175-186, 1972.

A study was made of the effect of perfusing prostaglandin E_1 (0.9 μg/kg/min) through a 15 cm mixing segment and a 30 cm study segment of jejunum on transit time and net and unidirectional flow of water and electrolytes in 10 subjects (8 men and 2 women, aged 21-51 yr) with no gastroinestinal lesions or clinical abnormalities of transit time. An isotonic solution consisting of 100 mM NaCl, 4 μCi ^{22}Na, 100 μCi HTO, 10 g/liter polyethylene glycol 4000, and 100 mM mannitol was perfused at a rate of 10 ml/min. Each subject served as his own control. Prostaglandin E_1 significantly increased net secretion of water, sodium, chloride, potassium, and bicarbonate into the intestinal lumen. The effect of this prostaglandin on the net flux of water and sodium was due primarily to an increase in the unidirectional flow from blood to lumen and not to an increase in the transit time through the jejunum. The striking similarities between the effects of rostaglandin E_1 and cholera toxin on net and uni- rectional flow of fluid and electrolytes suggest lat both of these agents may act upon the same ecretory mechanism in the intestine.

612 INTESTINAL ABSORPTION OF INTACT PROTEINS IN NORMAL AND PROTEIN-DEFICIENT RATS. *(E.)*

rthington, B. S.; Boatman, E. S.; Kenny, G. E. Sch. Public Hlth. Commun. Med., Univ. Washington, eattle). *Am. J. Clin. Nutr.* 27(3):276-286, 1974.

ntestinal absorption of macromolecules was assessed control and protein-deficient Sprague-Dawley rats sing serological and morphological procedures. Ani- als weighing approximately 120 g were divided into groups and given a 0.5% or an 18% lactalbumin diet. monthly intervals following diet initiation, 8 an- als from each group were examined for their capacity absorb proteins from the small intestine. Five the 8 animals in each group received an oral dose bovine serum albumin (BSA, 0.8 mg/g) 4 hr prior blood collection. The remaining 3 animals were dministered horseradish peroxidase via ligated je- unal loops before loop excision and processing for lectron microscopy. Immunoelectro-osmophoresis of era revealed that, whereas both control and protein- eficient rats absorbed measurable quantities of BSA, rotein deficiency promoted an increase in transport. orphological evaluation of jejunal tissue from pro- ein deficient rats suggested initial increase in inocytotic activity with eventual deterioration of pical junctions and movement of protein molecules irectly between cells. In some protein-deficient ats BSA levels reached 500 μg. The physiological ignificance of these findings is unknown, but the ossibility exists that the animals may produce ntibodies to the circulating foreign proteins with esultant anaphylaxis or deposition of antigen- ntibody complexes in various body tissues.

613 THE INTESTINAL ABSORPTION OF DIETARY CHOLESTEROL BY HYPERCHOLESTEROLEMIC (TYPE II) ND NORMOCHOLESTEROLEMIC HUMANS. *(E.)*

Connor, W. .; Lin, D. S. (Univ. Iowa Coll. Med., Iowa City). . *Clin. Invest.* 53(4):1062-1070, 1974.

holesterol absorption was studied in 15 normocholes- erolemic and 6 hypercholesterolemic (type II) sub- ects fed background cholesterol-free formula diets ith 40% of calories as fat. Each test meal consis- ed of a breakfast into which was incorporated scram- led egg yolk containing 300-500 mg of cholesterol nd (4^{-14}C)cholesterol (3-22 μCi), either naturally ncorporated into the yolk cholesterol by previous sotope injection into the laying hen or added in eanut oil to the yolk of the test breakfast. In ome instances ($1\ \alpha$-^{3}H)cholesterol was the radioac- ive marker. The radioactivity of the fecal neutral terol fraction was determined in daily stool samples or the next 7 days to provide an estimate of unab- orbed dietary cholesterol. The amount of absorbed nd reexcreted labeled cholesterol was negligible. ost unabsorbed dietary cholesterol appeared in the tool on the second or third day after the meal, nd 95% or more was recovered in the stool by 6 days. lasma specific activity curves were usually maximal at 48 hr. Normal subjects absorbed 44.5% of the administered cholesterol. Hypercholesterolemics absorbed the same percentage of cholesterol as normals: 47.6%. Absorption was similar whether the radiolabeled cholesterol was added to egg yolk or naturally incorporated in it. Six normal subjects were fed a cholesterol-free formula for 4 weeks, and then different amounts of cholesterol (110-610 mg/day) were added for another 4 weeks. At the end of each period, single test meals containing either 110, 310, or 610 mg of cholesterol and (1α-^{3}H)cholesterol were administered. Cholesterol absorption was 42.3 and 45.4% for the 2 dietary periods, resp. The absolute cholesterol absorption was linearly related to the amount of cholesterol in the test meal, and absorption was not affected by background diets high or low in cholesterol content.

2614 A RE-EVALUATION OF THE IMPORTANCE OF PARTITION COEFFICIENTS IN THE GASTROINTESTINAL ABSORPTION OF NUTRIENTS. *(E.)*

Houston, J. B.; Upshall, D. G.; Bridges, J. W. (Biochem. Dept., Univ. Surrey, Guildford, England). *J. Pharmacol. Exp. Ther.* 189(1):244-254, 1974.

The gastrointestinal absorption of a homologous series of carbamates was investigated in male adult Porton rats using both *in vitro* and *in situ* techniques. *In vitro* data indicated that the intestinal absorption rate increased when the chain length of the carbamate was extended from methyl to *n*-butyl. A further increase in the chain length resulted in a fall in the absorption rate. The amount of carbamate tissue bound was also maximal for *n*-butyl carbamate. Mucosal loss was calculated from the amount of carbamate transferred plus that which was tissue-bound. At chain lengths up to *n*-butyl, the percentages transferred and tissue-bound were relatively constant at 85% and 15%, resp. At longer chain lengths, the percentage remaining in the tissue increased at the expense of the percentage transferred. No metabolism was detected during the passage through the gut *in vitro*. In *in situ* experiments, all carbamates exhibited monoexponential loss from the lumen. Absorption rates for *n*-butyl carbamate were not dependent upon variations in mucosal concentrations or competition from other carbamates (ethyl, *tert*-butyl and *n*-hexyl). Thus, the absorption process appeared to be passive. The concept of an optimal partition coefficient for intestinal absorption is discussed in terms of a 2-compartment model where a hydrophilic barrier and a lipoidal membrane control the rate of absorption. The gastric absorption rates of the same series of compounds did not share the same optimal partition coefficient.

2615 ABSORPTION OF LECITHIN AND LYSOLECITHIN BY THE GALLBLADDER. *(E.)*

Neiderhiser, D. H.; Morningstar, W. A.; Roth, H. P. (VA Hosp., Cleveland, Ohio). *J. Lab. Clin. Med.* 82(6):891-897, 1973.

The absorption of uniformly labeled ^{14}C-lecithin and ^{14}C-lysolecithin in guinea pig bile by the guinea pig gallbladder *in situ* was studied. Over a concentration range of 0.1 to 1.0 mM, 20 to 12% of instilled lecithin was absorbed. At a concentration of 0.1 mM, 50% of instilled lysolecithin was absorbed by the gallbladder. Recovery of radioactivity was greatest (33%) from the gallbladder wall and most of the radioactivity (70%) was present in lecithin rather than in lysolecithin. Histologic examination of gallbladder sections demonstrated no abnormality after instillation of 1.0 mM lecithin or 0.1 mM lysolecithin. Increasingly severe histologic changes were associated with instillation of 0.5 and 1.0 mM lysolecithin. These changes consisted of focal erosion and ulceration of the mucosa; edema of the lamina propria; diffuse and focal neutrophilic infiltration; an increased number of lymphocytes and plasma cells which were scattered, focal, perivascular, and follicular in distribution; varying degrees of hyperemia; and extravasation of erythrocytes.

2616 ABSORPTION OF TWO TRIPEPTIDES BY THE HUMAN SMALL INTESTINE: A STUDY USING A PERFUSION TECHNIQUE. *(E.)* Silk, D. B. A.; Perrett, D.; Webb, J. P. W.; Clark, M. L. (St. Bartholomew's Hosp., London, England). *Clin. Sci. Mol. Med.* 46(3):393-402, 1974.

A double-lumen perfusion technique was used in man to study intestinal absorption of 2 tripeptides, glycylglycyl-glycine and L-alanyl-glycyl-glycine. Intraluminal tripeptide hydrolysis was investigated by incubating both tripeptides *in vitro* with fresh uncentrifuged saline aspirates. Glycine was absorbed faster from a glycyl-glycyl-glycine solution (3.3 mmol/liter) than from an equivalent (10 mmol/liter) glycine solution, and both L-alanine and glycine were absorbed faster from 10 mmol/liter L-alanyl-glycylglycine than from the equivalent amino acid mixture. Free amino acids and dipeptides were aspirated during the tripeptide perfusions. L-Alanyl-glycyl-glycine was hydrolyzed faster than glycyl-glycyl-glycine *in vitro*, and results indicated that hydrolysis of the tripeptides occurred from the N-terminal end of the molecule. Intraluminal tripeptide hydrolysis was not sufficient to account for the concentrations of free amino acids and dipeptides liberated during the tripeptide perfusion experiments *in vivo*. It is suggested that the liberated amino acids and dipeptides either diffused back into the luminal contents after hydrolysis in the brush border had taken place, or effluxed from the mucosal cell after intracellular tripeptide hydrolysis.

2617 THE DEPENDENCE OF LIPID ABSORPTION *IN VIVO* IN SOLUBILIZED CONCENTRATION. *(E.)* Lee, K. Y.; Hurley, D. M.; Simmonds, W. J. (Dept. Physiol., Univ. Western Australia, Nedlands). *Biochim. Biophys. Acta* 337(2):214-224, 1974.

The variation of the *in vivo* absorption of lipid with the concentration solubilized in the lumen was studied. Two types of perfusates were prepared in which the total concentration of absorbable labeled lipid and of conjugated bile acid was the same. Absorption was tested in rats prepared in 2 ways: 1) unanesthetized with common bile duct and thoracic lymph duct cannulated in which lipid was continuously perfused by duodenal cannula; and 2) anesthetized with the small intestine cannulated proximally below the entrance of the common bile duct and distally in the lower third of the ileum. In the second preparation, the whole perfusate was injected at zero time and an even exposure to the entire mucosa ensured by to and fro displacement. In the first preparation, absorption of (^{14}C)oleic acid and glyceryl (^{3}H)monooleyl ether into the lymph was the same for both lipids and both perfusates. Lipid was almost completely absorbed before the perfusate reached the distal half of the small intestine. In the second preparation, disappearance of lipid from the lumen and uptake by the mucosa was less for the perfusate in which the concentration solubilized was lower. Oleic acid was absorbed more rapidly than monoether, relative to the concentrations solubilized. These findings agreed with results for everted sacs *in vitro*. It is suggested that in the first preparation, decreased absorption per unit area can be compensated by utilization of more of the total absorptive area. In the second preparation and in everted sacs, no such compensation is possible and variation in absorption rate with solubilized concentration can be readily demonstrated.

2618 STUDIES OF GLYCEROL TRANSPORT ACROSS THE RABBIT BRUSH BORDER. *(E.)* Rubin, A. W.; Deren, J. J. (Dept. Med., Univ. Pennsylvania, Philadelphia). *Gastroenterology* 66(3):378-383, 1974.

The unidirectional movement of glycerol across New Zealand rabbit brush border was studied *in vitro*. The permeability coefficient for glycerol across the ileal brush border decreased from 3.41 x 10^{-4} cm/sec at 0.05 mM to 0.65 x 10^{-4} cm/sec at 5 mM, and remained constant at this level from 5-50 mM. Glucose (10 mM) and phlorizin (0.5 mM) did not inhibit glycerol movement. N-ethylmaleimide (10 mM) inhibited glycerol transport from a 0.05 mM solution by more than 55%, but did not affect glycerol uptake from a 50 mM solution. Glycerol movement across the ileal brush border, measured from a 0.05 mM solution, was twice as great as the movement across proximal intestine. In contrast, glycerol movement across proximal and distal intestine was similar when measured from a 50 mM solution. It is concluded that glycerol movement occurs both by diffusion *via* the aqueous regions of the membrane and by a saturable carrier-mediated mechanism.

2619 COLONIC ABSORPTION OF VITAMIN K-3. *(E.)* Hollander, D.; Truscott, T. C. (Albany Med. Coll., N.Y.). *J. Lab. Clin. Med.* 83(4):648-656, 1974.

Colonic transport of vitamin K-3 was investigated *in vitro* using everted, perfused, colonic segments from Sprague-Dawley rats. Stepwise increase in mucosal vitamin K-3 concentration up to 900 μM resulted in linear increase in the transport rate. Basal absorption rate of the vitamin under oxygen atmosphere at a mucosal concentration of 300 μM was 10.99 nmol/min/100 mg of dry tissue. Transport rate under nitrogen atmosphere, or with 10^{-4} M 2,4-dinitrophenol, or with 3 x 10^{-3} M sodium azide did not decrease. Using the same experimental preparation, a fatty acid,

ctanoate, was transported well across the colon,
ut no transport of a water-soluble alcohol, eryth-
itol, took place. Vitamin transport ceased in the
bsence of a concentration gradient across the colo-
ic mucosa. This study strongly indicates that rat
olonic absorption of vitamin K-3 takes place *via* a
assive transport process; a similar passive trans-
ort mechanism has been noted for small bowel ab-
orption of vitamin K-3 in the rat.

620 EFFECT OF ESSENTIAL FATTY ACID DEFICIENCY ON AMINO ACID UPTAKE BY THE SMALL INTESTINE F RATS. *(E.)* Johns, J. T.; Bergen, W. G. (Dept. nim. Husb., Michigan State Univ., East Lansing). . *Nutr.* 104(3):300-305, 1974.

he role of essential fatty acid (EFA) deficiency on ntestinal amino acid transport was studied in prague-Dawley rats. Extracellular space (measured y inulin) became constant after a 40-min *in vitro* ncubation of intestinal rings from rats fed the ontrol diet but continued to increase for rats fed he EFA-deficient diet for 12-14 week. The K_m and /$_{max}$ values of lysine and methionine transport were ot affected by diet. However, the amino acid dis- ribution ratios (capacity of cells to retain con- entrated amino acids) were lower for intestinal rings from EFA-deficient rats. Glucose (10 or 50 mM) inhibited methionine transport in both control and EFA-deficient intestinal rings. The data suggest that EFA deficiency induces membrane alterations in the intestinal mucosa that lower the ability of mucosal cells to retain amino acids.

2621 STUDIES ON THE INCREASED ABSORPTION OF OUBAIN, PHENOLSULPHONPHTHALEIN AND PRALIDOXIME CAUSED BY SODIUM LAURYL SULPHATE FROM SINGLE-LOOP PREPARATIONS IN THE RAT. *(E.)* Briseid, G.; Briseid, K.; Bergersen, B. (Inst. Pharm., Univ. Oslo, Norway). *Naunyn Schmiedebergs Arch. Pharmacol.* 282(1):45-57, 1974.

In concentrations above the critical micelle concentration (effective range about 2-22 mM), sodium lauryl sulfate caused graded increases in the absorption of ouabain, phenolsulfonphthalein, and pralidoxime by jejunal loops in anesthetized albino rats. Replacement of sodium chloride in the medium by sucrose or of Tyrode solution by a sodium phosphate buffer significantly reduced surfactant-induced increases in phenolsulfonphthalein and pralidoxime absorption. Replacement of sodium chloride by mannitol had little effect on surfactant-induced increases in ouabain absorption. No change occurred in the extent of absorption in the absence of surfactant. Increased absorption caused by sodium lauryl sulfate must be ascribed to a direct action on the intestinal membrane. These results indicate that surfactant-induced increases in phenolsulfonphthalein and pralidoxime absorption are Na-dependent.

2622 ON THE MECHANISM OF ISOOSMOTIC TRANSPORT OF FLUID ACROSS THE SMALL INTESTINE. THE EFFECT OF THE STAVERMAN REFLECTION COEFFICIENT OF THE SOLUTE USED TO INCREASE THE OSMOLALITY OF THE MUCOSAL SOLUTION ON THE COMPOSITION OF THE ABSORBATE. *(E.)* Beck, I. T.; Dinda, P. K. (Hotel Dieu., Kingston, Canada). *Can. J. Physiol. Pharmacol.* 52(1):96-104, 1974.

The mechanism by which fluid transport across the small intestine becomes isoosmotic with the mucosal solution was investigated. The osmolaity of the mucosal solution of a unilaterial preparation (the serosal side was not bathed) was increased with water-soluble nonelectrolyte solutes having different Staverman reflection coefficients (σ), and the composition of the undiluted absorbate was studied. The solutes (hyperosmotic agents) used were formamide, urea, erythritol, and mannitol. As shown by a method based on potential difference depression, the σ's of these solutes in the hamster small intestine were 0.26, 0.85, 0.93, and 1.00, resp. Data on transport across the unilateral preparation showed that when the intestine was incubated in an isotonic solution (Krebs-Ringer bicarbonate solution containing 10 mM glucose, 292 mosmol/kg), the absorbate was essentially isotonic although its composition differed significantly from that of the mucosal solution. When the osmolality of the mucosal solution was increased to 342, 393, or 442 mosmol/kg with any of the hyperosmotic agents, the absorbate was always isoosmotic with the mucosal solution. With formamide (low σ) as the hyperosomotic agent, the concentration of electrolytes and glucose in the absorbate was the same as that in control preparation (incubated in the isotonic mucosal solution), and the transported fluid became isoosmotic with the mucosal solution exclusively due to the presence of formamide in the absorbate. When the osmolality of the mucosal solution was increased with urea, erthrytol, or mannitol, the concentration of these hyperosmotic agents in the absorbate decreased linearly with the increase in their σ; the absorbate became isoosmotic with the mucosal solution due to a linear increase in the concentration of electrolytes and glucose. In addition, the transport of fluid, solutes, and fluid/solute decreased linearly with the increase in the hyperosomtoic agents. Further calculations indicated that the increase in the concentration of electrolytes and glucose with increase in σ of the hyperosmotic agents was due almost exclusively to a linear decrease in fluid/solute transport.

2623 1α,24-DIHYDROXYCHOLECALCIFEROL RECEPTORS IN INTESTINE. II. TEMPERATURE-DEPENDENT TRANSFER OF THE HORMONE TO CHROMATIN VIA A SPECIFIC CYTOSOL RECEPTOR. *(E.)* Brumbaugh, P. F.; Haussler, M. R. (Coll. Med., Univ. Arizona, Tucson). *J. Biol. Chem.* 249(4):1258-1262, 1974.

Specific binding of 1α,25-dihydroxycholecalciferol in the cytosol and purified chromatin fractions of chick small intestinal mucosa was studied to investigate the mechanism by which this hormone arrives at its chromatin binding site. The cytosol fraction of the mucosa contains a macromolecule with a high affinity for 1α,25-dihydroxycholecalciferol and has a limited number of binding sites which are saturated at low hormone concentrations (approximately 10^{-8} M). The association of the sterol with the cytoplasmic component is thermolabile, and is destroyed by treatment with pronase, but not by nucleases, and the receptor component is therefore presumed to be a protein. The protein-sterol complex was isolated and characterized by sucrose gradient centrifugation and sediments at 3 to 3.5 S in the presence of 9.15 M KCl. The interaction of 1α,25-dihydroxy[^{3}H] cholecalciferol with the cytosol protein is reversed by unlabeled 1α,25-dihydroxycholecalciferol > 25-hydroxycholecalciferol > 1 -hydroxycholecalciferol > cholecalciferol = estradiol-17β. The subcellular localization of 1α,25-dihydroxycholecalciferol is temperature-dependent. The hormone remains bound to the cytosol fraction at 0° in whole intestines *in vitro*, and a dramatic movement of 1α,25-dihydroxycholecalciferol to the nuclear chromatin occurs at 37°. The temperature dependence of the hormone localization is also evident in intestinal mucosa homogenates and reconstituted cytosol-chromatin systems. This observation suggests that the cell membrane and nuclear membrane are not involved in the temperature-dependent process. It is postulated that the specific cytosol receptor for 1α,25-dihydroxycholecalciferol functions to transport the hormone to its ultimate site of action in the nuclear chromatin. This receptor system is similar to those described for other steroid hormones, and lesions in the system may explain vitamin D-resistant diseases.

2624 1α,25-DIHYDROXYCHOLECALCIFEROL RECEPTORS IN INTESTINE. I. ASSOCIATION OF 1α,25-DIHYDROXYCHOLECALCIFEROL WITH INTESTINAL MUCOSA CHROMATIN.

(E.) Brumbaugh, P. F.; Haussler, M. R. (Coll. Med., Univ. Arizona, Tucson). *J. Biol. Chem.* 249(4):1251-1257, 1974.

Vitamin D$_3$ (cholecalciferol) is known to be metabolized to 1α,25-dihydroxycholecalciferol, and this sterol is thought to be the active form of the vitamin. Oral administration of increasing amounts of radioactive vitamin D$_3$ to vitamin D-deficient chicks resulted in a saturable binding of 1α,25-dihydroxycholecalciferol to the intestinal chromatin that paralleled saturation of the calcium absorption response. Saturation of the chromatin binding sites and maximum stimulation of calcium absorption occurred after a 20 I.U. dose of cholecalciferol. The appearance of 1α,25-dihydroxycholecalciferol in the chromatin precedes the calcium absorption response by 2 to 8 hr after a physiologic dose of 1α,25-dihydroxycholecalciferol (390 pmoles). This sterol also specifically associates with the chromatin fraction after incubation with intestinal mucosa homogenates *in vitro*. The chromatin fraction contains a finite number of binding sites for 1α,25-dihydroxycholecalciferol, and closely related sterols such as 25-hydroxycholecalciferol in equal concentration do not bind to this fraction; however, displacement of the hormone from the receptor can be achieved by concentrations of cholecalciferol = dihydrotachysterol$_2$ >> 1α-hydroxycholecalciferol > 25-hydroxycholecalciferol >> 1α,25-dihydroxycholecalciferol. Pretreatment of rachitic chicks with unlabeled vitamin D$_3$ or 1α,25-dihydroxycholecalciferol reduced the subsequent binding of radioactive 1α,25-dihydroxycholecalciferol to the intestinal chromatin *in vitro*. It is concluded that localization of the apparent hormonal form of vitamin D$_3$, 1α,25-dihydroxycholecalciferol, in the nucleus of the target tissue is probably involved in the physiologic response of calcium transport.

2625 DEMONSTRATION OF ELECTROGENIC Na$^+$-DEPENDENT D-GLUCOSE TRANSPORT IN INTESTINAL BRUSH BORDER MEMBRANES.

(E.) Murer, H.; Hopfer, U. (Dept. Biochem., Swiss Fed. Inst. Technol., Zurich). *Proc. Natl. Acad. Sci. USA* 71(2):484-488, 1974.

Na$^+$-coupled D-glucose transport was studied in isolated membrane vesicles from intestinal brush borders of Sprague-Dawley rats. Concentration gradients of SCN$^-$, K$^+$, and H$^+$ were established between the intravesicular solution and the incubation medium and their influence on D-glucose uptake from the medium was measured. A gradient (medium > vesicle) of NaSCN, but not of KSCN, produced a transient overshoot of D-glucose uptake above the equilibrium level. Similarly, an increase of the membrane conductance with valinomycin (K$^+$-conductance) or with uncoupling agents of oxidative phosphorylation (H$^+$-conductance) induced an overshooting D-glucose uptake, provided a (vesicle > medium) K$^+$-gradient or a H$^+$-gradient, resp., was present in each case. The transient overshoot is evidence that D-glucose was taken up against its concentration gradient (up to 10-fold). The gradients of SCN$^-$, K$^+$ (in the presence of valinomycin), and H$^+$ (in the presence of uncouplers) are thought to contribute to this active D-glucose transport by changing the electrical potential across the vesicle membrane and thus making the inside more negative (with respect to the medium). These experiments, therefore, provide evidence that the Na$^+$-coupled D-glucose translocation across the brush border membrane is an electrogenic process, i.e., the positive charge associated with Na$^+$ is not compensated by the co-movement of an anion or the counter-movement of a cation *via* the glucose carrier. The results imply that an electrical potential across the brush border membrane may play an important role in determining the transport of D-glucose by intact cells.

2626 MONOGLYCERIDE MODIFICATION OF JEJUNAL ABSORPTION OF FATTY ACID IN THE RAT.

(E.) Marubbio, Jr., A. T.; Morris, Jr., J. A.; Clark, S. B.; Holt, P. R. (St. Luke's Hosp. Ctr., New York, N. Y.). *J. Lipid Res.* 15(2):165-172, 1974.

The effect of increasing the intracellular pool of mono-olein on the subsequent uptake and esterification of oleic acid was investigated using *in vitro* rat jejunal slice techniques. The mucosal pool of monoglyceride was expanded by preincubation of jejunal slices in a bile salt medium containing 2-monoelexl glycerol at a temperature close to 1 C, which inhibited esterification. Subsequent incubation in micellar [^{14}C]oleic acid was performed either at 37 C or in the cold. Monoglyceride preincubation increased [^{14}C]oleic acid uptake by about 60% without increasing incorporation of fatty acid into triglyceride. This was not due to inhibition of esterifying capacity nor to changes in oleic acid binding to a mucosal fatty acid-binding protein. It is suggested that under these experimental conditions monoglyceride may modify intracellular pools of fatty acid. However, when monoglyceride and fatty acid were preincubated together, mucosal esterification rates during subsequent incubation at 37 C more than doubled. The data suggest that although the unstirred water layer around mucosal cells may be a barrier to the movement of fatty acid it is not rate limiting for overall fatty acid flux from the medium and into the cell.

2627 EFFECTS OF 25-HYDROXYVITAMIN D_3 ON RAT DUODENUM, JEJUNUM, AND ILEUM: CORRELATION OF CALCIUM ACTIVE TRANSPORT WITH TISSUE LEVELS OF VITAMIN D_3 METABOLITES. *(E.)* Walling, M. W.; Favus, M. J.; Kimberg, D. V. (Michael Reese Hosp. Med. Ctr., Chicago, Ill.). *J. Biol. Chem.* 249(4):1156-1161, 1974.

Jejunum and ileum from vitamin D-deficient Sherman rats actively secreted calcium when studied *in vitro*, while duodenum from these animals actively absorbed calcium. Acute repletion with a single physiologic dose of 25-hydroxyvitamin D_3 (25-OH D_3) (15 IU) increased calcium absorption in duodenum and ileum but had no effect on jejunum. Studies of the distribution of 25-OH D_3 and its metabolites in these tissues demonstrated that levels of 1,25-$(OH)_2$ D_3 per cell were highest in duodenum, much lower in ileum, and lower still in jejunum. The increased calcium absorption in duodenum and ileum was proportional to the levels of 1,25-$(OH)_2D_3$ in these tissues. This was not the case for jejunum however, because while 1,25-$(OH)_2$ D_3 was present, calcium transport rates were unchanged. Another finding was a much higher percentage of water-soluble metabolites of 25-OH D_3 in jejunum and ileum than in duodenum. This observation may relate to an enterohepatic circulation of these compounds. These experiments suggest that previous reports of decreased calcium absorptive responses by lower small bowel (relative to proximal duodenum) to treatment with vitamin D, or prolonged dietary calcium deprivation, can be explained by the differential cellular localization of 1,25-$(OH)_2$ D_3 (duodenum > ileum > jejunum).

2628 NUTRITIONAL SIGNIFICANCE OF THE EFFECT OF A HIGH-SODIUM DIET ON INTESTINAL GLYCINE ABSORPTION IN THE RAT. *(Fr.)* Peres, G. E.; Cier, J. F.; Peres, G. (Fac. Med., Lyon, France). *C. R. Soc. Biol. (Paris)* 167(8/9):1146-1149, 1973.

MOTILITY

671 GASTRIC EMPTYING IN HEALTHY SUBJECTS AND
IN PATIENTS WITH VARIOUS MALABSORPTIVE
TATES. *(E.)* Moberg, S.; Carlberger, G. (St. Erik's
osp., Stockholm, Sweden). *Scand. J. Gastroenterol.*
(1):17-21, 1974.

astric emptying of a 300-ml test liquid meal con-
aining fat, carbohydrate, and protein was measured
n 7 healthy controls and in 8 patients with steator-
hea, 4 of whom had distal resections of the small
ntestine, 2 chronic pancreatitis, and 2 celiac di-
ease. The gastric emptying curve for the healthy
ubjects could be divided into a short, rapid phase
nd a much slower second phase during which a con-
tant amount of the test meal was emptied per min.
n patients with severe steatorrhea, the gastric
mptying of the fat-containing meal used here closely
esembled that of healthy subjects emptying an inert
est meal. Thus no inhibition of the rapid gastric
mptying rate was noted in these patients. The 1
atient with marked pancreatic insufficiency had no
easureable amount of trypsin in the intestinal contents. Thus it may be deduced that the lipase activity was insufficient. This theory is supported by the finding of extremely small amounts of free fatty acids in the upper small intestine of this patient. Therefore the failure of this patient to retard gastric emptying might have been caused by inadequate digestion of fat. The 2 patients with extensive small bowel resections had high fecal fat content and a fast gastric emptying rate. It is felt that such patients have a defective micelle formation of the fat, which is essential in order to elicit the retarding impulses. It is suggested that these 2 patients did not reach the critical micellar concentration. Of the patients with gluten-enteropathy, it was suggested that lack of bile and disturbed micelle formation may have caused the defective inhibition of the gastric emptying rate. Regardless of the cause, the patients with the largest disturbances of fat absorption showed the largest deviation from the normal gastric emptying pattern. These findings agree with the assumption that gastric emptying of a test meal of the type used here is regulated by fat absorption.

2672 REFLEX ADRENERGIC INHIBITION OF GASTRIC MOTILITY ELICITED FROM THE GASTRIC ANTRUM.

(E.) Abrahamsson, H. (Dept. Physiol., Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 90(1):14-24, 1974.

The reflex effects of distension and contraction of the gastric antrum on corpus-fundus motility were studied in 30 anesthetized cats. Besides a vagally mediated reflex corpus-fundus relaxation, antral distension elicited prompt reflex inhibition of corpus-fundus contractions; this also occurred after vagotomy. In vagotomized animals this inhibitory reflex also persisted after cervical spinal cord transection, but was abolished by spinal anesthesia or by guanethidine (3-5 mg/kg). Stepwise increases in antral distension revealed that the reflex corpus-fundus inhibition appeared at distending pressures of 5-10 cm H_2O, then increased in a graded fashion, and could be maintained for at least 10 min if a steady distension was applied. Isometric antral contractions were also effective in eliciting reflex corpus-fundus inhibition. It is concluded that activation of slowly adapting "tension receptors" in the antral gastric wall inhibits gastric (corpus-fundus) motility via a spinal reflex mechanism, mediated by splanchnic adrenergic fibers that suppress intramural excitatory cholinergic neurons. This gastrogastric adrenergic inhibitory reflex seems to be activated concomitantly with a vago-vagal gastro-gastric relaxation reflex. These two suppressive reflex mechanisms may play an important role in regulation of gastric motor function.

2673 CHOLINESTERASE HISTOCHEMISTRY OF THE INNERVATION OF THE SMOOTH MUSCLE SPHINCTERS AROUND THE TERMINAL INTRAMURAL PART OF THE DUCTUS CHOLEDOCHUS IN THE CAT AND THE DOG.

(E.) Kyosola, K. (Dept. Anat., Univ. Helsinki, Finland). *Acta Physiol. Scand.* 90(1):278-280, 1974.

The microarchitecture of the choledocho-duodenal junction, together with the distribution of acetylcholinesterase and nonspecific cholinesterases, was studied in 25 adult cats and 5 adult dogs. In the lamina propria of the duodenum, including the core of the villi, an irregular network of varicose nerve fibers was observed. The muscularis muscosae of the duodenum was innervated by a dense nerve plexus of richly beaded, delicate nerve fibers; in the dog this nerve plexus also contained large nerve fascicles or nerve trunks and a few small ganglia. Acetylcholinesterase-positive ganglia were abundant in the submucosa of the duodenum. In the cat a nerve plexus with small ganglia was observed in the basal 2/3 of the lamina glandularis mucosa of the common bile duct. This layer was devoid of acetylcholinesterase activity in the dog, like the epithelium in both species. In both species, the smooth muscle and the ganglia in the submucosa of the duodenum or within the sphincters, as well as the nerves in these layers and in the lamina propria of the duodenum, were strongly positive for nonspecific cholinesterases. The lamina glandularis muscosae of the canine common bile duct was devoid of such activity, whereas several types of nonspecific cholinesterase-positive structures were seen in the cat. The epithelium of the common bile duct was devoid of nonspecific cholinesterase activity in both species. The results are indicative of active complex motor functions of the choledocho-duodenal junction, in contrast to only slow gross contractions of the intestine.

2674 A COMPARISON BETWEEN PRIMARY ESOPHAGEAL PERISTALSIS FOLLOWING WET AND DRY SWALLOWS.

(E.) Dodds, W. J.; Hogan, W. J.; Reid, D. P.; Stewart, E. T.; Arndorfer, R. C. (Med. Coll. Wisconsin, Milwaukee). *J. Appl. Physiol.* 35(6):851-857, 1973.

Esophageal peristalsis associated with wet and dry swallows was studied in 18 young adult subjects, using both infusion (1.6 ml/min) and noninfusion manometric techniques. For both recording techniques, wet swallows elicited a higher incidence of normal peristaltic sequences than did dry swallows. Quantitative differences in peristaltic variables existed between peristalsis associated with wet versus dry swallows. In the distal half of the esophagus, a wet swallow was associated with a significantly greater amplitude and duration of the peristaltic pressure complex, a slower wave speed, and a longer duration of lower sphincter relaxation than was a dry swallow. These findings may be accounted for by differences in bolus volume, esophageal stretch, or in the physical work necessary to move a bolus mass into the stomach against the abdominal-thoracic pressure gradient. It is concluded that differences in the incidence and quantitative features of peristalsis associated with wet versus dry swallows should be considered when designing protocols for esophageal manometry or when comparing results from different studies.

2675 THE ACTION OF SECRETIN, TRYPSIN AND HISTAMINE ON THE MOTILITY OF CANINE INTESTINAL VILLI.

(E.) Nemeth, E. P.; Thasz, M.; Folly, G.; Papp, M. (Semmelweis Univ. Med. Sch., Budapest, Hungary). *Am. J. Gastroenterol.* 60(6):607-615, 1973.

Gradually increasing doses of secretin, trypsin, and histamine were injected into the artery of the 1st jejunal loop in dogs to determine the number of villous contractions and to study early effects on the capillaries and the jejunal mucous membrane. Secretin significantly increased and trypsin reduced the number of intestinal villous contractions. Less than 1 μg of histamine increased the number of contractions, and 1 μg caused a decrease. Larger doses of secretin (8-16 U), trypsin (250 μg), and histamine (5 μg) elicited spastic contractions of the intestinal villi. In the villi and the intestinal mucous membrane these agents produced ischemia, followed by dilatation of the capillaries, stasis, and pericapillary bleeding. Both in its manifestation and its extent, this early vascular reaction greatly resembled impairment of microcirculation in the mucous membrane occurring in experimental pancreatitis. It is suggested that secretin, trypsin, and histamine may inhibit the motor function of the stomach and jejunum in acute pancreatitis.

SECRETION AND METABOLISM

2688 MOLECULAR REGULATION OF DIGESTION: SHORT TERM AND BOND SPECIFIC. *(E.)* Rothman, S. S. (Sch. Med., Univ. California, San Francisco). *Am. J. Physiol.* 226(1):77-83, 1974.

The effect of lysine on the secretion of trypsinogen, which splits lysine-containing peptide bonds, was tested as a function of its route of administration (intestinal, i.v., or *in vitro*). Duodenal perfusion of 1 x 10^{-4} M lysine moderately increased overall protein secretion but did not alter the secretion of trypsinogen relative to chymotrypsinogen. Lysine (1 x 10^{-3} M) increased the proportion of trypsinogen in secretion, but overall protein secretion was no longer enhanced. I.v. lysine also increased trypsinogen secretion relative to chymotrypsinogen but did not affect overall protein output. Unlike its *in vivo* administration, lysine added directly to medium bathing whole pancreas *in vitro* acted as a negative feedback influence favoring the secretion of chymotrypsinogen over trypsinogen. Selective secretion was observed within 40 min and appears to be the result of changes in the transport of enzymes rather than their synthesis. The data suggest that short-term (within meal), bond-specific regulation of digestion may occur for the trypsinogen-lysine pair by both positive and negative feedback mechanisms acting at the acinar cell and at other sites.

SECRETION AND METABOLISM

Stomach

2700 AN EXPERIMENTAL STUDY OF THE ANTRAL GASTRIN MECHANISM. *(E.)* Friesen, S. R.; Crosby, I.; Boggan, M. D.; Fiallos, E.; Lees, J. M.; Cudnik, D. B.; Underwood, III, J.; Peckler, M. S.; Craig, C. C.; Friesen, R. H.; Bolinger, R. E.; McGuigan, J. E. (Univ. Kansas Sch. Med., Kansas City). *Surgery* 75(4):517-527, 1974.

Over a 4-yr period experiments were carried out in 120 dogs in which the gastric antral mucosa was subjected, on a chronic basis, to 9 different environmental conditions in 3 general categories of influence: antral "stimulation," antral "inhibition," and "neutral" (Neither antral stimulation nor inhibition). To substantiate the endocrine function of the antrum, the influence of the antral mucosal environment on antral gastrin release was measured directly by repeated serum gastrin concentrations and indirectly by gastric acid concentrations and the incidence of ulceration. The antrum of the dog was responsive to chronic experimental stimulation by distention and by alkaline secretions of the colon, duodenum, and gallbladder, as evidenced by significant elevations of serum gastrin concentrations and by an increase in the incidence of acid-peptic ulceration. When the antrum is in juxtaposition to acid-secreting gastric mucosa, no significant increases in serum gastrin content occur; furthermore, if the antral mucosa is chronically exposed to histamine-provoked acid hypersecretion, significant reductions in serum gastrin content are observed, suggesting inhibition of antral gastrin release. The antral mucosa is dynamically responsive to experimental changes in its environment without evidence of fatigue within the observed experimental period of 6 months.

2701 INCREASED RESPONSIVENESS OF GASTRIC MUCOSA TO GASTRIN STIMULATION IN THE ECK FISTULA RAT. *(E.)* Kutz, K.; Herz, R.; Halter, F.; Leuenberger, J.; Bircher, J. (Dept. Clin. Pharmacol., Univ. Berne, Switzerland). *Gastroenterology* 66(1):73-78, 1974.

To further analyze the gastric hypersection occurring after a portacaval shunt, gastric acid output was measured in 20 anesthetized male Sprague-Dawley rats randomly divided into an experimental group which was subjected to a portacaval shunt, and an unoperated group of similar age. Fourteen days after end to side portacaval anastomosis, intravenous injections of 8, 16 and 32 ng of human gastrin I resulted in significantly higher total and peak acid outputs than in appropriate control rats. The time course of gastric secretion revealed no evidence for a shunt-induced alteration in the rate of gastrin degradation. Therefore, the data suggest that, in shunted rats, the parietal cell mass is more sensitive to gastrin stimulation than in control rats.

2702 STIMULATION BY 2-DEOXY-D-GLUCOSE AND INHIBITION BY INSULIN OF GASTRIC SECRETION IN FISTULA CHICKENS.

(E.) Burhol, P. G. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 8(8): 761-764, 1973.

The effect of i.v. injection of 2-deoxy-D-glucose (100, 200, and 400 mg/kg) and insulin (2.5, 5, and 10 U/kg) on basal gastric secretion was studied in 10 fistula Plymouth Rock chickens. A dose of 200 mg/kg 2-deoxy-D-glucose was required before gastric water, H^+, and pepsin secretion increased significantly after nearly 60 min. In dogs, gastric secretion increases 20 min after a 50 mg/kg dose. The gastric secretion in the chicken is subject to vagal stimulation. Insulin showed a dose-dependent and significant inhibition of the gastric secretion of water and H^+, but not of pepsin secretion. Insulin inhibits the gastric secretion by a direct action on the gastric transport of water and H^+. It is concluded that fistula chickens can be used as a model to study the inhibitory effect of insulin unopposed by any central stimulatory effect.

2703 MUCOSAL CYCLIC AMP AND SECRETION IN THE DOG STOMACH.

(E.) Mao, C. C.; Jacobson, E. D.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Am. J. Physiol.* 225(4):893-896, 1973.

The following hypothesis was evaluated, that an elevation of gastric mucosal cyclic AMP is essential for initiation of acid secretion. The preparation was a flap of fundic dog stomach *in situ*. Intra-arterial and intravenous infusion of histamine and pentagastrin initiated brisk secretion of acid from the stomach, but neither agent changed mucosal cyclic AMP content. The potent phosphodiesterase inhibitor, papaverine, significantly increased canine gastric mucosal cyclic AMP concentration when infused intra-arterially but did not evoke any secretion of acid. The findings suggest that cyclic AMP is not the mediator of acid secretion in the dog stomach.

2704 CALCIUM-SECRETAGOGUE INTERACTION IN THE STIMULATION OF GASTRIC ACID SECRETION.

(E.) Kasbekar, D. K. (Georgetown Univ. Sch. Med. Dent., Washington, D. C.). *Proc. Soc. Exp. Biol. Med.* 145(1):234-239, 1974.

Gastric epithelia of R. catesbeiana were depleted of Ca^{2+} in the continued presence of secretagogues by removing this cation from the bathing media and repeated washouts with or without EDTA until acid secretion was reduced to zero. Under these conditions, both the transmucosal potential difference and resistance declined. Incubation of these epithelia in presence of 1 m*M* Ca^{2+} in the luminal bathing medium resulted in a partial reversal of potential difference and resistance with initiation of some secretion, in contrast to near complete reversal obtained following restoration of Ca^{2+} to the serosal bathing medium. Dibutyryl cyclic-AMP or theophylline enhance acid secretion in these circumstances without complete reversal of potential difference and resistance. These observations suggest that cellular Ca^{2+} may play a direct role in the production of H^+ *per se* by mediating the secretagogue effect in raising intracellular cyclic-AMP levels, in addition to its established role in the maintenance of integrity of junctional complexes which are essential for the luminal segregation of H^+ in the secretory process.

2705 EFFECT OF RED CHILLI POWDER ON DNA CONTENT OF GASTRIC ASPIRATES.

(E.) Desai, H. G.; Venugopalan, K.; Antia, F. P. (Nair Charitable Hosp., Bombay, India). *Gut* 14(12):974-976, 1973.

The DNA content in gastric aspirate was measured in the basal state and after infusion of 1.6 and 0.8 g/hr of red chilli powder into the stomach through a double-lumen tube. During one hour, 400 ml of normal saline was slowly infused and the gastric aspirate was collected. The measured quantity of red chilli powder was added to 500 ml of normal saline and was slowly infused through the tube for the next hour and the gastric aspirate was collected. The DNA content was measured with diphenylamine reagent. The subjects included controls, patients with duodenal ulcer in remission and patients with chronic gastritis. There was a highly significant increase in the DNA in gastric aspirate after intragastric infusion of red chilli powder. The results suggest a rapid and marked exfoliation of gastric surface epithelial cells in human subjects given red chilli powder.

2706 DOES BURIMAMIDE INHIBIT GASTRIC ACID SECRETION BY A RELEASE OF CATECHOLAMINES?

(E.) Albinus, M.; Sewing, K.-Fr. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 279(4):417-420, 1973.

The effect of burimamide (4 mg/kg, i.v.) on histamine-stimulated gastric acid secretion and gastric mucosal blood flow (GMBF) was estimated in anesthetized gastric fistula cats. Both histamine-stimulated gastric acid secretion and GMBF were reduced by about 65% by burimamide; GMBF was reduced for a longer period of time than was gastric acid secretion. The inhibitory effect of burimamide on gastric acid secretion was reduced by phenoxybenzamine (4 mg/kg, i.v.) administered 1 hr prior to the infusion of histamine. The burimamide injection also elevated systolic and diastolic blood pressure and increased cardiac frequency. The blood pressure response was antagonized by the α-receptor blocking agent phentolamine and the cardiac response was antagonized by the β-receptor blocking agent propranolol. The blood pressure response to burimamide was also markedly reduced by acute adrenalectomy. The effect of burimamide on gastric acid secretion was not antagonized by phentolamine, propranolol, or adrenalectomy. The effects of burimamide on the stomach can be at least partially explained in terms of a release of catecholamines.

2707 STRUCTURE-ACTIVITY RELATIONSHIPS OF GASTRIN: CONTRIBUTION OF THE CARBOXYL GROUPS OF 9- AND 10-GLUTAMIC ACID TO BIOLOGICAL ACTIVITY.

(Ger.) Wissmann, H.; Schleyerbach, R.; Schoelkens, B.; Geiger, R. (Farbwerke Hoechst AG, Frankfurt/Main, Germany). *Hoppe Seylers Z. Physiol.* 354(12):1591-1598, 1973.

Four short-chain analogues of human gastrin I were synthesized to determine whether the presence of γ-carboxyl groups in positions 9 and 10 of gastrin have any effect on the biological activity of this hormone. Biological activity was studied by measuring gastric acid secretion during perfusion of the stomachs of fasted anesthetized male Wistar rats *in situ* and by measuring the effects of these peptides on a variety of cardiovascular parameters. Acylation of the C-terminal tetrapeptide of gastrin with radicals which are resistant to enzymatic hydrolysis caused a significant enhancement in the stimulation of gastric acid secretion. A further increase in biological activity was obtained by N-terminal elongation of the peptide chain up to positions 6-10 which consist of 5 glutamic acid esters and by exchanging methionine for leucine in the 15 position. This increase also occurs if a single γ-carboxyl group is introduced, in the form of a 4-carboxybutyryl group. Introduction of a second carboxyl group causes only a slight additional increase in biological activity. These short-chain gastrin analogues had a less pronounced effect on the cardiovascular system than pentagastrin.

2708 CHANGES IN GASTRIC ACID AND PEPSIN SECRETION IN RATS WITH SUBACUTE ULCERS OF THE STOMACH AND DUODENUM. NEW EXPERIMENTAL MODEL.

(Sp.) Monfort Albelda, R.; Sanchez de la Cuesta y Alarcon, F.; Alemany Ontiveros, J. R.; Aznar Lopez, J. (Fac. Med., Sevilla, Spain). *Rev. Esp. Enferm. Apar. Dig.* 41(7):771-778, 1973.

Subacute ulcers were induced in fasted male Sprague-Dawley rats by subserosal injection of 0.03-0.04 ml of 10% acetic acid into the stomach or the first part of the duodenum. Then physiological saline was injected i.p. to destroy excess acetic acid and to prevent peritoneal adhesions. Rats were fed a normal diet after 4-7 days, and total acidity, pH, and pepsin activity were measured by a modification of Lai's technique in which distilled water was instilled i.v. (0.38 ml/hr). Effluent perfusion fluid was strongly acid in rats with ulcers, particularly in those with ulcers of the duodenum. Although there was a highly significant difference in the pH between rats with gastric and duodenal ulcers, the difference in total acidity was not significant. This suggests that the decrease in pH is due primarily to an increase in HCl secretion in rats with duodenal ulcers and to an increase in the secretion of organic acids in rats with gastric ulcers. The proteolytic activity of the gastric effluent was significantly higher in rats with gastric ulcers than in those with duodenal ulcers. This suggests that in gastric ulcer there is a larger supply of substrate in the form of unchanged pepsinogen; this is determined as pepsin. This animal model is recommended for the study of the effects of drugs on peptic ulcers since it is a good approximation of peptic ulcers in man.

2709 CALCITONIN INHIBITION OF GASTRIC SECRETION IN RAT.

(E.) Orimo, H.; Oyama, T.; Ito, H. (Metropolitan Geriatr. Hosp., Tokyo, Japan). *Endocrinol. Japon.* 20(5):439-446, 1973.

In a series of 3 experiments, male Wistar rats were left untreated, subjected to pyloric ligation, injected s.c. with porcine thyro-calcitonin (1 MRC U) before and/or during pyloric ligation, or subjected to surgical removal of the parathyroid gland prior to pyloric ligation. Thyrocalcitonin markedly inhibited the accumulation of gastric acid and the development of acute gastric ulcer in the pylorus ligated rats; this effect was dose dependent. The gastric output in the parathyroidectomized animals was not significantly different from that in the intact animals, indicating that hypocalcemia does not necessarily cause the inhibition of gastric acid secretion in the rat. Since a lower dose of thyrocalcitonin (0.0625 MUC U) caused a significant inhibition of gastric acid accumulation 6 hr after s.c. injection (at which time its hypocalcemic effect had disappeared), the inhibitory effect of thyrocalcitonin on the secretion of gastric acid may be due to a direct effect of the thyrocalcitonin and may not be due to the hypocalcemia caused by this hormone. Although prior treatment with thyrocalcitonin prevented the development of ulcer in rats subjected to 9 hr of pyloric ligation, this effect was markedly reduced when the ligation is extended to 12 hr. It is therefore possible that acute gastric ulcer in the pylorus ligated rat is produced by the increased secretion of gastric acid. Thyrocalcitonin may be useful in preventing the development of peptic ulcer.

2710 IMMUNOSYMPATHECTOMY AND GASTRIC SECRETION.

(E.) Rivilis, J. (Jewish Gen. Hosp., Montreal, Canada). *Arch. Surg.* 107(4):618-621, 1973.

Immunosympathectomized (IS) Wistar rats did not differ from normal controls in terms of weight, volume of gastric juice secreted in 2 hr/100 g of rat, or peptic activity. However, the celiac ganglia of the IS rats were only 70-80% the size of those of the controls, and the cell density of the IS ganglia was much lower than in the controls, the cells in the IS ganglia having been partially replaced by connective tissue. The nuclei of the remaining cells in the IS animals were grossly abnormal. Shallow ulcers and hyperemia in the glandular portion of the stomach appeared in 4 of the 5 IS rats after pyloric ligation for 2 hr and the 5th IS rat had marked hyperemia. There were no macroscopic or microscopic changes in the stomachs of the controls. The data indicate that the sympathetic nervous system plays little or no part in the production of acid or pepsin. However, it appears to play an important part in the protective mechanism of the gastric mucosa.

2711 PENTAGASTRIN-STIMULATED PEPSIN SECRETION IN MAN AND DOGS. *(E.)* Magee, D. F. (Creighton Univ., Sch. Med., Omaha, Neb.). *Ann. Surg.* 179(3):300-303, 1974.

Pentagastrin (6.0 μg/kg s.c.) significantly increases the secretion of pepsin in asymptomatic unoperated controls and in patients following recent or old vagotomy. In recent vagotomy patients, both stimulated and unstimulated acid and pepsin were significantly lower than in controls or old vagotomy patients. The stimulated and unstimulated acid in the recent vagotomies was significantly lower than in patients with ulcer craters or scarring. Basal pepsins in the recent vagotomies did not differ from those in the unoperated symptomatic groups. The stimulated pepsins in the recent vagotomies were marginally reduced compared to the visible crater group. They were not reduced compared to the other 2 symptomatic groups. Pentagastrin increased the secretion of pepsin in vagotomized dogs. The Heidenhain pouch does not mirror the behavior of pepsin in the intact or vagotomized stomach.

2712 BASAL AND PENTAGASTRIN-STIMULATED GASTRIC ACID SECRETION IN CHINESE, INDIAN AND MALAY SUBJECTS. A COMPARATIVE STUDY. *(E.)* Fung, W. P.; Tye, C. Y. (Univ. Singapore, Dept. Med.). *Am. J. Gastroenterol.* 60(5):488-495, 1973.

Pancreas

2727 DEGENERATION OF MOUSE PANCREATIC ACINAR CELLS DURING FASTING. *(E.)* Nevalainen, T. J.; Janigan, D. T. (Dept. Pathol., Dalhousie Univ., Halifax, Canada). *Virchows Arch.* [*Zellpathol.*] 15(2):107-118, 1974.

Ultrastructural changes in the pancreas of C57BL/10J mice were studied after 1, 2, and 3 days of fasting. A gradual decrease in zymogen granule numbers was evident after a 1 day fast and was pronounced after 2-3 days. As zymogen granule size decreased, a new population of small granules, approximately 0.2-0.3 μ in diameter, appeared in the apical cytoplasm. They were especially numerous in the vicinity of the Golgi cisternae and were apparently Golgi vacuoles filled with secretory material. Autophagic activity increased in the Golgi areas but there were no signs of intracellular degradation of zymogen granules. After a 3 day fast, focal cytoplasmic degeneration was marked and many acinar cells were nectrotic. By this time serum and pancreatic amylase levels were about 25% and 18%, resp., of the levels in nonfasted controls. The extensive degenerative changes occurring after modest periods of fasting emphasize the need for careful interpretation of experimental studies where fasting is used to establish a baseline for studies on the exocrine pancreas.

2728 UNRESPONSIVENESS OF EXOCRINE RAT PANCREAS TO CALCEMIC CHALLENGES (HYPERCALCEMIA, EDTA HYPOCALCEMIA OR CALCITONIN ADMINISTRATION) WHICH INFLUENCE STOMACH FUNCTION. *(E.)* Ziegler, R.; Minne, H.; Zwicker, M.; Hotz, J. (Ctr. Intern. Med. Pediatr., Univ. Ulm, Germany). *Res. Exp. Med. (Berl.)* 162(4):347-350, 1974.

In female albino rats secretin and pancreozymin (each 2.5 U/100 g/hr i.v.) stimulated exocrine pancreatic secretion at a level which was maintained for almost 3 hr. Pancreatic enzyme secretion was not altered by hypercalcemia induced by calcium gluconate (2 mg Ca^{++}/100 g/hr i.v.), Na_2EDTA (5 mg/100 g/hr i.v.), or porcine thyrocalcitonin (200 MRCmU/100 g/hr i.v.). Administration of calcium increased serum calcium by 2.5 mEq/liter, while administration of EDTA and thyrocalcitonin decreased it by 1.5 mEq/liter. The unresponsiveness of the rat pancreas to calcium stimulation is in contrast to the reaction of the human pancreas and also to the reaction of the rat stomach. The reason for these organ and species differences is not known.

2729 HORMONAL AND DIETARY ADAPTATION OF RAT PANCREATIC HYDROLASES BEFORE AND AFTER WEANING. *(E.)* Deschodt-Lanckman, M.; Robberecht, P.; Camus, J.; Baya, C.; Christophe, J. (Brussels Univ. Sch. Med., Belgium). *Am. J. Physiol.* 226(1):39-44, 1974.

All levels of digestive enzymes did not change in constant proportion in the pancreas of albino rats before weaning, and different stimuli were probably responsible for their emergence. The high levels of amylase and chymotrypsinogen observed during the late fetal period were followed by a marked depression in the newborn period. Prompt administration of hydrocortisone (5 mg/100 g for 7 days, i.p.) prevented the drop of these hydrolases and enhanced the low activity of trypsinogens in 1- to 23-day-old pups. This observation together with the reported decreasing activity of the pituitary-adrenal axis during the first neonatal weeks suggests that glucocorticoid secretion is a stimulus effective in evoking a series of pancreatic hydrolases. The emergence of lipase was slow, responding poorly to hydrocortisone and to nutritional controls only after 25 days. L-Thyroxine (2 μg i.p.), glucagon (50 μg i.p.) or dibutryryl cyclic AMP (125 μg i.p.) were unable to increase the specific activities of all hydrolases tested. Nutritional controls were predominant in regulating levels of hydrolases in adult rats. The time course of variation in specific activities of amylase and lipase on high-corn oil and high-starch diets was unaffected by 7 days of glucagon administration. Adrenalectomy tended to decrease and hydrocortisone treatment tended to increase the level of pancreatic amylase in rats submitted to the same dietary manipulations. The accumulation of amylase required the presence not only of starch but also of protein in the diet.

2730 BILIARY AMYLASE OUTPUT IN RATS WITH PANCREATIC DUCT OBSTRUCTION AND CCL_4-INTOXICATION. *(E.)* Maezawa, H.; Ogawa, S.; Ito, Y. (Tokyo Med. Dental Univ., Japan). *Proc. Japan Acad.* 49(3):208-212, 1973.

The effects of hyperamylasemia *in vivo* on biliary amylase output were examined in rats with special attention to the interrelations among bile flow, plasma amylase level, and biliary amylase. Experimental hyperamylasemia was produced by pancreatic duct obstruction and by CCl_4-intoxication. Amylase level in the bile was elevated. There was a positive correlation to plasma amylase level in rats with pancreatic duct obstruction or chronic CCl_4-intoxication. Biliary amylase output was increased and there was a positive correlation to amylase level in the bile in untreated rats and in rats with pancreatic duct obstruction. However, in rats with chronic CCl_4-intoxication there was no significant increase in biliary amylase output although amylase level was significantly elevated both in the bile and in the blood plasma. Amylase level in the bile was elevated by chronic CCl_4-intoxication, and there was a positive correlation with plasma levels of transaminase. A significant decrease in urinary excretion of amylase was also observed in rats with chronic CCl_4-intoxication. The results in the CCl_4-treated subgroup suggested that biliary amylase level was elevated secondarily to the high plasma amylase level which was probably due to the decrease in urinary output. The increase in biliary amylase output, which was most probably due to the decrease in bile flow, revealed no statistically significant difference from that in the control subgroup.

2731 EXOCRINE PANCREATIC INSUFFICIENCY: A NEW RECESSIVE MUTATION IN MICE.

(E.) Pivetta, O. H.; Green, E. L. (Jackson Lab., Bar Harbor, Me.). *J. Hered.* 64(5):301-302, 1973.

Spontaneous exocrine pancreatic insufficiency was found in 3 of 2329 inbred CBA/J mice and in none of 15,462 mice from 12 other inbred strains. The affected animals were found in 3 litters from 3 different brother-sister matings; all affected animals traced back to a common ancestral pair a few generations earlier. The segregation data from matings within the CBA/J strain support the contention that the trait is due to an autosomal recessive mutation, while segregation data from outcross matings indicate that other genes affect the expression of the trait. The affected homozygotes are recognized at 2 to 3 weeks of age by their small body size and yellow, fatty feces. The feces have almost no trypsin-like activity and have an elevated total fat content. The pancreatic tissue is almost completely replaced by fat, but the islets of Langerhans appear histologically normal. The blood glucose levels are below normal, although no glycosuria has been detected.

2732 PANCREATIC PERFUSION IN THE PATHOPHYSIOLOGY OF HEMORRHAGIC SHOCK.

(E.) Spath, Jr., J. A.; Gorczynski, R. J.; Lefer, A. M. (Univ. Virginia Sch. Med., Charlottesville). *Am. J. Physiol.* 226(2):443-451, 1974.

The *in situ* hemodynamically isolated, autoperfused, or pump-perfused pancreas of mongrel dogs was used to study the effect of hemorrhage on pancreatic blood flow, pancreatic resistance, plasma proteolysis, and the plasma activity of a myocardial depressant factor. In autoperfused dogs, pancreatic blood flow fell 82% early in shock and remained at this level throughout 3 hr of oligemia. Pancreatic ischemia was associated with a 2- to 3-fold increase in β-glucuronidase activity and amino N levels in plasma, a 27-fold increase in cathepsin D activity, and a 3- to 4-fold increase in myocardial depressant factor activity. Pump perfusion of the pancreas at normal flow during shock limited the increases in the activities of β-glucuronidase and cathepsin D and in amino-N concentration of plasma to half that found in autoperfused hemorrhaged dogs and almost completely prevented the rise in plasma myocardial depressant factor activity. Nevertheless, pancreatic vascular resistance rose 71%, with active constriction evident during the first hr of hemorrhage. These results indicate that severe prolonged pancreatic hypoperfusion contributes significantly to lysosomal disruption, proteolysis, and production of myocardial depressant factor and therefore to the deleterious sequelae of circulatory shock.

2733 EXOCRINE SECRETORY RESPONSES OF THE PANCREAS TO PENTAGASTRIN AND TO A MEAT MEAL IN DOGS.

(E.) Gupta, S.; Elder, J. B.; Gillespie, I. E. (Western Infirm., Glasgow, Scotland). *Digestion* 9(6): 482-489, 1973.

The pancreatic responses of 4 dogs with pancreatic and gastric fistulae were studied with i.v. infusion of pentagastrin in doses maximal for gastric acid secretion (4-8 μg/kg/hr), and separately with a 400-g meat meal. With the gastric fistula open, there was a small increase in pancreatic bicarbonate, and a marked increase in protein output, after pentagastrin. With the gastric fistula closed, bicarbonate and protein outputs to pentagastrin were not significantly different from those seen in response to a meat meal. These results suggest that when the gastric fistula is closed, pentagastrin infusion at doses maximal for gastric acid secretion stimulates the pancreas to a degree closely similar to that produced by a 400-g meat meal. This similiarity may be due to a combination of a direct action of pentagastrin on the pancreas and an indirect action by means of gastric acid secretion reaching the duodenum and causing secretin release.

2734 THE INFLUENCE OF THE SPLANCHNIC NERVES ON THE EXTERNAL SECRETION, BLOOD FLOW AND ELECTRICAL CONDUCTANCE OF THE CAT PANCREAS.

(E.) Barlow, T. E.; Greenwell, J. R.; Harper, A. A.; Scratcherd, T. (Dept. Anat. Physiol. Univ. Newcastle upon Tyne, England). *J. Physiol.* 236(2): 421-433, 1974.

Electrical stimulation of the cut peripheral end of the splanchnic nerves of cats results in a biphasic change in electrical conductance measured across the tail of the pancreas. A phase of decreased conductance is followed by a more prolonged phase of increased conductance. Simultaneous measurements of pancreatic blood flow indicate that the phase of decreased conductance is a result of vasoconstriction, while the phase of increased conductance is due to vasodilatation. The initial phase of decreased conductance and vasoconstriction is abolished by α-receptor blocking agents such as phenoxybenzamine (0.5-20 mg i.v.) and the phase of increased conductance blocked by β-receptor blocking agents such as pronethalol (0.5-10 mg i.v.). Short periods of electrical stimulation applied to the splanchnic nerves result in a secretion of amylase and a reduction in the volume rate of secretion. When the vasoconstrictor response was abolished by phenoxybenzamine, nerve stimulation still reduced the rate of secretion, suggesting that the inhibitory effect is in part due to a direct action of the secretory cells. After bretylium tosylate (0.4-12.4 mg i.v.), splanchnic nerve stimulation no longer produced vasomotor changes in the pancreas and the inhibitory effect on the volume response was converted to one of augmentation, but the secretion of enzymes was unaffected. The secretion of amylase on splanchnic stimulation was abolished by atropine (1 mg/kg i.v.), suggesting that a cholinergic mechanism is involved. Noradrenaline(5 μg/kg) did not mobilize pancreatic enzymes.

2735 EFFECT OF ACTINOMYCIN D, PANCREOZYMIN AND SECRETION ON RNA SYNTHESIS AND PROTEIN SYNTHESIS MEASURED IN VIVO IN RAT PANCREAS.

(E.) Reggio, H.; Cailla, H. L. (Univ. Provence, Marseille, France). *Biochim. Biophys. Acta* 338(1):37-42, 1974.

The effect of actinomycin (2 mg/kg i.p.) on RNA synthesis in pancreas of Wistar rats was studied with or without pentobarbital, secretin, and pancreozymin. Actinomycin alone inhibited (^{3}H)adenine incorporation into salt-insoluble RNA by 96.3%. Similar inhibition of RNA synthesis occurred when actinomycin was injected into rats treated with pentobarbital (60 mg/kg i.p.) or given pentobarbital and infused with secretin and pancreozymin (0.75 Ivy dog U/kg/hr). Treatment with pentobarbital alone induced a 70% decrease in (^{3}H)adenine incorporation; a similar decrease occured when rats were infused with pancreozynin and secretin in addition to pentobarbital. When (^{3}H)adenine was replaced by (^{32}P)orthophospate, similar results were obtained with both pancreas and liver. Incorporation of L-(^{14}C)valine into protein decreased by about 50% when rats were treated for 4 hr with actinomycin. Pentobarbital alone or in the presence of the secretogogue hormones reduced valine incorporation by 80%. Pancreozymin enhanced protein synthesis and its effect was not modified by actinomycin. Stimulation of protein synthesis by pancreozymin even in the absence of any DNA-dependent RNA synthesis suggests that the hormone does not act at the level of the transcription process. It is proposed that pancreozymin induces an increase in the number of active mRNA molecules or acts at the level of the translation process.

2736 EFFECT OF AMINONUCLEOSIDE ON THE ACTIVITY OF PANCREATIC PROTEASES. *(E.)* Mayer, M.; Ochieng, N.; Khassis, S.; Shafrir, E. (Hebrew Univ.-Hadassah Med. Sch., Jerusalem, Israel). *Biochim. Biophys. Acta.* 338(2):447-457, 1974.

The activation of trypsinogen and chymotrypsinogen was studied in pancreatic extracts from normal male albino rats and from hypoproteinemic rats given 7 daily s.c. injections of 2.0 mg/100 g aminonucleoside of puromycin [6-dimethylamino-9-(3'-amino-3'-deoxy-β-D-ribofuranosyl)-purine]. Upon incubation of the pancreatic extracts, the usual 2-3 hr lag phase of the sigmoidal-shaped activation curve was almost abolished in the aminonucleoside-treated rats. The maximal activity of the two proteases obtained after complete activation was unaffected. The early onset of the autocatalytic appearance of tryptic or chymotryptic activity appeared to be due to the presence of preformed trypsin-like activity in the pancreatic extracts of the aminonucleoside-treated animals. A short-term treatment with aminonucleoside (single 6 mg/100 g dose), which did not lead to proteinuria and hypoproteinemia, also resulted in an increased trypsin/trypsinogen ratio in the pancreas and a shortening of the lag period. A direct concentration-dependent effect of the drug was demonstrated in *in vitro* experiments, showing a release of hydrolytic enzymes from isolated pancreatic zymogen granules. A direct effect of aminonucleoside on the pancreas may also be involved in the protease-induced membrane labilization seen after aminonucleoside treatment.

2737 THE EFFECT OF ETHIONINE ON THE ENERGY-PRODUCING METABOLISM IN THE RAT PANCREAS. II. ALTERATIONS OF TISSUE LEVELS OF ADENINE NUCLEOTIDES, PYRIDINE NUCLEOTIDES, AND GLYCOLYTIC METABOLITES. *(E.)* Goebell, H. (Dept. Intern. Med., Univ. Ulm, Germany). *Horm. Metab. Res.* 6(1):44-49, 1974.

The effect of 4 different does of d,l-ethionine (0.05 mg, 0.25 mg, 0.5 mg, and 1 mg/g body weight) on pancreatic tissue levels of ATP, ADP, AMP, nicotinamide adenine dinucleotide, phosphate and glycolytic metabolites 5 hr after i.p. application was investigated in female Wistar rats. Doses of 0.25-1 mg resulted in a similar, significant decrease in level of adenine and pyridine nucleotides and of most substrates measured. The content of lactate was increased, as was the lactate/pyruvate ratio. These effects were also present after a dose of 0.05 mg/kg but were far less marked. This indicates a saturation of the mechanism responsible for the deficit of nucleotides when the dosage exceeds 0.25 mg/g. One mg ethionine/g induced the same alterations even after 2 hr. They were still present 12 hr after administration. In 2 experiments, 0.05 mg and 0.25 mg/g of ethionine were given i.p. once daily over period of 4 days; on the fourth day, the same metabolic alterations were found in the pancreas which had been seen 5 hr after application of 0.25-1 mg/g. The reduction of the tissue content of ATP to about 50% of the control level is the main cause of a disturbance in the intracellular enzyme transport, leading to an accumulation of enzyme protein in the cells. However, it is not the sole cause of this phenomenon or of the progressive destruction of the cell, as these phenomena are dependent on the applied dose of ethionine. The metabolic alterations are not dose dependent above a certain saturating level of the toxic agent.

2738 PURE CHOLECYSTOKININ: PANCREATIC PROTEIN AND BICARBONATE RESPONSE. *(E.)* Debas, H. T.; Grossman, M. I. (Univ. California Sch. Med., Los Angeles). *Digestion* 9(6):469-481, 1973.

In dogs with chronic pancreatic fistulas, pure cholecystokinin (3000 Ivy dog μ), a highly purified variant, 20% pure cholecystokinin, an octapeptide of cholecystokinin, and caerulein all gave the same high maximal protein outputs and low maximal bicarbonate outputs. Ten percent pure cholecystokinin gave higher bicarbonate output than can be achieved with pure cholecystokinin. By intestinal perfusion, HCl gave greater protein output than can be achieved with secretin alone; sodium oleate gave greater bicarbonate output than can be achieved with pure cholecystokinin alone; and tryptophan gave maximal bicarbonate output less than that of pure cholecystokinin. On the hypothesis that intestinally perfused stimulants act solely by release of secretin and cholecystokinin, the effects of tryptophan can be accounted for by release of cholecystokinin alone, of HCl by release mainly of secretin plus small amounts of cholecystokinin, and of oleate by release mainly of cholecystokinin plus small amounts of secretin.

2739 THE EFFECT OF ISOPROTERENOL ON ENZYME SECRETION FROM THE ISOLATED PERFUSED CAT PANCREAS. *(E.)* Pederson, R.; Schulz, I. (Max Planck Inst. Biophys., Frankfurt, Germany). *Biochim. Biophys. Acta* 338(2):440-446, 1974.

The effects of D-(-)-propranolol, L-(+)-propranolol, choline chloride, phentolamine, and eserine sulfate on the enzyme secretion induced by acetylcholine, cholecystokinin-pancreozymin, and isoproterenol were studied in the isolated perfused feline pancreas. The pancreatic secretion of amylase was stimulated by acetylcholine (100 mg), cholecystokinin-pancreozymin (0.25 Ivy Dog U), and isoproterenol (10-50 μg). The isoproterenol-induced secretory response was abolished by the D-(-)-, but not the L-(+)-form, of the β-adrenergic blocker propranolol (10^{-5} M). The isoproterenol-induced response was also inhibited by atropine (1.4 X 10^{-7} M), but was unaffected by the α-blocking agent phentolamine (10^{-5} M). When the amylase response to isoproterenol was exhausted, it returned following perfusion of the pancreas with eserine sulfate (5 mg/liter) and choline chloride (3 mg/liter); neither eserine sulfate nor choline chloride were effective alone. The data indicate that isoproterenol acts on pancreatic β-receptors and that endogeneously released acetylcholine is responsible for the enzyme secretion.

2740 THE EFFECT OF VARIOUS SECRETAGOGUES ON ACCUMULATION OF CYCLIC AMP AND SECRETION OF α-AMYLASE FROM RAT EXOCRINE PANCREAS. *(E.)*

Heisler, S.; Grondin, G.; Forget, G. (Dept. Physiol., Univ. Sherbrooke, Canada). *Life Sci.* 14(4):631-639, 1974.

The effect of various secretagogues on accumulation of cyclic AMP was studied in relation to their ability to stimulate secretion of α-amylase in rat pancreatic fragments. Carbachol significantly lowered the tissue content of cyclic AMP in the pancreas from the third to the fifth minute of incubation. The response to pancreozymin was biphasic. An initial stimulation with a peak percentage increase in nucleotide levels was observed after 2 min of incubation. There followed a subsequent decrease in nucleotide levels; after 5 min of incubation, the cyclic AMP levels in pancreozymin-stimulated tissue was signficantly lower than in the controls. Theophylline increased tissue AMP by 85% after 1 min of incubation. Secretin also increased cyclic AMP content within the first minute of incubation. Secretion of α-amylase from unstimulated tissue was fairly constant throughout the experiment. Theophylline did not significantly stimulate secretion of α-amylase from the pancreas. Carbochol increased the output of α-amylase even after 1 min of incubation. Pancreozymin stimulated secretion of α-amylase beginning at the fifth minute of incubation. Secretin increased the release of α-amylase over control values at each point of observation (after 1 min to 10 min of incubation).

2741 SELECTIVE PANCREATIC ENZYME SECRETION DUE TO A NEW PEPTIDE CALLED CHYMODENIN. *(E.)*

Adelson, J. W.; Rothman, S. S. (Dept. Physiol., Univ. California, San Francisco). *Science* 183(4129):1087-1089, 1974.

The effect of i.v. administration of a newly isolated peptide, chymodenin, purified from porcine duodenum, upon the secretion of enzyme from the pancreas of the anesthetized rabbit was studied *in situ*. Administration of the peptide dramatically increased the secretion of chymotrypsinogen (ChTg) within 15 min, whereas lipase output remained unchanged and only a modest increase in protein output was observed. Male albino New Zealand rabbits were anesthetized. After cannulation of the pancreatic duct and an initial 1-hr stabilization period, secretion was collected for sequential 20-min periods, and all collected samples were analyzed for protein, ChTg, lipase, and fluid output. Chymodenin was administered i.v. at a dose of 10 μg in 1.0 ml of 0.9% NaCl per animal. Chymotrypsinogen output was increased approximately 3-fold following chymodenin administration in the basal lipase output range. Even in endogenously stimulated glands, the relative proportion of ChTg in the secreted protein mixture increased in some experiments. Within the first 15-min period, ChTg specific activity increased above the preceding preinjection period and returned to or below preinjection levels by 45 to 60 min. The response was clearly visible at the lowest dose employed, 100 ng of chymodenin/kg of body weight. As expected, pancreatic lipase output in the basal range was not augmented by injection of the peptide. Injection of chymodenin also increased protein output by about 40% in this range of low lipase output. In endogenously stimulated samples, no enhancement of ChTg or protein was observed following peptide injection. Mean lipase output was lower in the endogenously stimulated range, but not significantly lower. *In vitro* studies on the effect of chymodenin on enzyme output by the rabbit pancreas show a response similar to the *in situ* studies: a marked increase in ChTg output, no change in lipase secretion, and a moderate protein response. The observation that a peptide, chymodenin, purified from duodenal extracts elicits a specific increase in ChTg secretion from the exocrine pancreas suggests that the regulation of digestive enzyme secretion may be enzyme-specific and raises the possibility that other peptides with analogous functions may exist.

2742 CONCENTRATION OF PANCREOZYMIN AS A DETERMINANT OF THE EXOCRINE-ENDOCRINE PARTITION OF PANCREATIC ENZYMES. *(E.)*

Saito, A.; Kanno, T. (Fac. Vet. Med., Hokkaido Univ., Sapporo, Japan). *Jap. J. Physiol.* 23(5):477-495, 1973.

The 'exocrine-endocrine partition' of enzymes and their precursors was investigated in both the isolated and perfused rat pancreas, and the rat pancreas *in situ*. The release of amylase was accompanied by the release of precursors of proteolytic enzymes either into the common duct or into the portal vein, and it was measured as a representation of release of pancreatic enzymes. When the isolated pancreas was perfused with Krebs-Henseleit solution containing pancreozymin 0.2 U/ml, the amylase output into the common duct was markedly increased, whereas the output into the vein was slightly increased. When the concentration of pancreozymin was increased to 1.5 U/ml, the output into the vein was markedly increased in contrast to a small increase in the output into duct. Corresponding with the increase in output into the vein, acinar cells exhibiting high effective membrane resistances increased in number during perfusion of pancreozymin at a high concentration. Enhanced release due to pancreozymin into the vein and into the duct was negated when calcium was omitted from the perfusing medium. As a high dose of pancreozymin was injected repeatedly into the rat *in situ,* the blood concentration of amylase became higher but the increase in the output into the common duct became lower. It is concluded that pancreatic enzymes and precursors preserved in zymogen granules may be extruded into the acinar lumen by the common calcium-dependent cellular processes; then, some of the secretory products may leak into the portal vein *via* enlarged intercellular spaces when a high concentration of pancreozymin is present.

2743 THE EFFECTS OF GLUCAGON ON THE EXOCRINE SECRETION OF THE PERFUSED CANINE PANCREAS. *(E.)* Murphy, J. J.; McGeeney, K. F. (Dept Surg., Univ. College, Dublin, Ireland). *Ir. J. Med. Sci.* 143(1):37-41, 1974.

The action of glucagon (1 mg) on exocrine secretion of the totally isolated extracorporeal hemoperfused pancreas was studied in 19 mongrel dogs. The response to secretin (IU) and secretin plus glucagon were not significantly different for volume, amylase, lipase, and trypsin. The effect of glucagon on the pancreatic secretory response to CCK-Pz (6U) was not statistically significant. Following a large dose of secretin (20U) and CCK-Pz, there was a significant increase in the mean amylase output and in trypsin output. These results do not indicate an inhibitory role for glucagon in the isolated canine pancrease. From the amylase and trypsin responses to the combined secretin/CCK-Pz doses, it is possible that glucagon exerts some potentiation.

2744 DIRECT EFFECTS OF ALCOHOL ON IN VIVO AND IN VITRO EXOCRINE PANCREATIC SECRETION AND METABOLISM. *(E.)* Solomon, N.; Solomon, T. E.; Jacobson, E. D.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Am. J. Dig. Dis.* 19(3):253-260, 1974.

The effects of alcohol on *in vivo* and *in vitro* pancreatic secretion and cellular metabolism were studied in New Zealand white rabbits. I. v. ethanol (1 g/kg over 30 min) inhibited pancreatic secretion of water and bicarbonate and reduced tissue ATP content, but had no significant effect on protein secretion or tissue cyclic AMP content. Peak blood alcohol level after i.v. infusion was 70 mg/100 ml and correlated in each animal with the period of maximal inhibition of secretion. Ethanol, 3% (w/v), in the bathing fluid of the *in vitro* rabbit pancreas decreased water, bicarbonate, and protein output by 3%; greatly reduced tissue ATP content; and had no effect on cyclic AMP levels. These results support a hypothesis of inhibition of exocrine pancreatic secretion by a direct effect of ethanol on secretory cells and suggest that cellular metabolism is the locus of ethanol's action.

2745 THE EFFECTS OF INTRAGASTRIC ETHANOL ADMINISTRATION UPON CANINE EXOCRINE PANCREATIC SECRETION. *(E.)* Tiscornia, O. M.; Gullo, L.; De Barros Mott, C.; Devaux, M. A.; Palasciano, G.; Hage, G.; Sarles, H. (Res. Unit Digestive Pathol., INSERM, Marseille, France). *Digestion* 9(6):490-501, 1973.

The effects of intragastric administration of ethanol on exocrine pancreatic secretion were assessed in 11 mongrel dogs provided with gastric and pancreatic fistulas (Thomas cannula). The gastric fistula was left open throughout the experiments to prevent gastric content from entering the duodenum. Ethanol (12% in saline) decreased the protein concentration and the output of basal pancreatic secretion. Ethanol (40% in saline) showed no effect on pancreatic secretion stimulated by a continuous i.v. injection of GIH secretin (1.0 U/kg/hr but produced a significant increase in protein concentration and output when pancreatic secretion was stimulated by a continuous i.v. injection of Boots secretin (4.0 U/kg/hr). Intragastric infusion of 80% (v/v) ethanol under i.v. injection of GIH secretin (1.0 U/kg/hr) produced an inhibition of the flow rate and alkaline secretion and a significant increase in protein concentration and output. The latter response was suppressed by previous antrectomy.

2746 RELATIONS BETWEEN EXOCRINE PANCREATIC FUNCTION AND THE CALCIUM BALANCE IN MAN. *(Ger.)* Hotz, J.; Minne, H.; Ziegler, R. (Ctr. Intern. Med. Pediatr., Univ. Ulm, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1420-1423, 1972.

2747 INTERACTION OF PHOSPHOLIPASE A_2 AND ITS ZYMOGEN WITH DIVALENT METAL IONS. *(E.)* Pieterson, W. A.; Volwerk, J. J.; De Haas, G. H. (Biochem. Lab., State Univ. Utrecht, The Netherlands). *Biochemistry* 13(7):1439-1445, 1974.

SECRETION AND METABOLISM

Hepatobiliary Tract

2752 THE METABOLISM OF THE ISOLATED PERFUSED CANINE LIVER. *(E.)* Bhanalaph, T.; Sampson, D.; Murphy, G. P. (Roswell Park Mem. Inst., Buffalo, N. Y.). *Cryobiol.* 10(6):497-501, 1973.

Adult mongrel dogs were divided into 6 treatment groups: Group 1, liver perfusion; Group 2, deoxycorticosterone acetate (1 mg/day i.m.) for 7 days prior to liver perfusion; Group 3, testosterone (50 mg/day i.m.) for 7 days prior to liver perfusion; Group 4, carbon tetrachloride (5 ml p.o.) every day for 5 days prior to liver perfusion; Group 5, right thoractomy for partial constriction of the intrathoracic inferior vena cava prior to liver perfusion; Group 6, common bile ligation prior to liver perfusion. The mean liver oxygen consumption did not differ significantly between Groups 1-4, while the oxygen consumption was not significantly increased in Group 5 and significantly increased in Group 6. The carbon dioxide production from anaerobic metabolism did not differ among the groups. When fructose was added to the incubation substrate, the production of carbon dioxide decreased significantly in groups 4 and 6 and decreased nonsignificantly in group 2. These data point up the hazard in relying on hepatic metabolic performance to differentiate between the presence or absence of certain disease states or drug treatments known to have important hepatic consequences.

2753 ALCOHOL AND SUCROSE IN CHOLINE DEFICIENCY CIRRHOSIS IN THE RAT. *(E.)* Patek, Jr., A. J.; Bowry, S. C.; Anuras, S. (VA Hosp., Boston, Mass.). *Arch. Pathol.* 96(6):377-382, 1973.

Weanling male Wistar rats were maintained on protein and choline deficient liquid diets in which alcohol constituted 35% of the total calories. A second group of rats was maintained on a liquid diet in which sucrose replaced the alcohol isocalorically. The sucrose fed rats developed cirrhosis, while the alcohol fed animals developed minimal fatty changes in the liver and showed no increase in connective tissue. The mechanism of this inhibitory effect is not clear. The alcohol may have increased the degree of inanition or decreased the metabolic activity to such a degree that the need for choline became minimal. In an experimental model combining choline deficiency and alcohol excess, the interplay of these two hepatotoxic factors may distort the effect of either factor alone on the liver.

2754 HYDROXYLATION OF TAUROLITHOCHOLATE BY ISOLATED HUMAN LIVER MICROSOMES. I. IDENTIFICATION OF METABOLIC PRODUCT. *(E.)* Trulzsch, D.; Roboz, J.; Greim, H.; Czygan, P.; Rudick, J.; Hutterer, F.; Schaffner, F.; Popper, H. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.). *Biochem. Med.* 9(2):158-166, 1974.

Liver microsomes prepared from human biopsy specimens were incubated with reduced nicotinamide adenine dinucleotide phosphate and taurolithocholate. The microsomes hydroxylated the taurolithocholate, with the hydroxylation occurring in the 6α position. The reaction product was identified as hyodeoxycholic acid. The identification was based on the following observations: the product formed during the incubation of taurolithocholate with isolated microsomes was shown in terms of its molecular weight and molecular composition to be a dihydroxy bile acid; the gas chromatographic retention times of the TFA and TMS derivatives of the produce were the same as that of hyodeoxycholic acid; and the mobility of the product during thin-layer chromatography was identical with that of hyodeoxycholic acid methyl ester but quite different from the mobility of the methyl ester of its 6β isomer, 3α-6β-dihydroxy-5β-cholanoic acid.

2755 EFFECT OF BILIARY TRACT OBSTRUCTION ON LIVER MICROSOMES IN THE RAT. *(E.)* Auranen, A.; Ahonen, J.; Hvitfelt, J. (Dept. Surg., Univ. Turku, Finland). *Eur. Surg. Res.* 5(3):228-232, 1973.

The common bile ducts of adult Wistar rats were ligated and the liver microsomes were prepared 3, 6, or 9 days later. The ligation of the ductus choledochus resulted in a significant increase in liver weight. The liver DNA content did not decrease, but the microsomal protein content did decrease, as did the activity of liver glucose-6-phosphatase and the demethylation of aminopyrine. Reductions were also seen in hexobarbital metabolism, microsomal RNA and phospholipid levels, microsomal cytochrome P-450 levels, reduced triphosphopyridine nucleotide-cytochrome C reductase activity, and the incorporation of ^{14}C-glycine into microsomal protein. The microsomal cytochrome b5 content did not decrease. The data indicate the disturbances in the protein synthesizing systems are seen only after 9 days of ligation.

2756 THE EFFECTS OF PERFUSION, AMINO ACIDS AND HORMONES ON THE FREE AND ENDOPLASMIC RETICULUM-BOUND RIBOSOMES OF RAT LIVER. *(E.)*

Kelman, L.; Saunders, S. J.; Wicht, S.; Firth, L. O'C. (Dept. Med., Univ. Cape Town, South Africa). *S. Afr. Med. J.* 47(38):1751-1753, 1973.

The effects of glucose, insulin, cortisone, pancreozymin, secretin, gastrin, growth hormone, glucagon, testosterone, and various amino acids on the free and endoplasmic reticulum-bound ribosomal profiles in the isolated perfused rat liver were studied. Both ribosomal populations disaggregated progressively during perfusion. Single amino acids failed to influence the ribosomal profile; however, arginine, asparagine, isoleucine, leucine, lysine, methionine, phenylalanine, proline, threonine, tryptophan, and valine in combination prevented the ribosomal disaggregation. The ribosomal profiles were not influenced by the infusion of growth hormone, cortisone, insulin, secretin, gastrin, glucagon, or glucose plus insulin. The ribosomal profiles of livers derived from fasted rats did not differ from those of livers derived from well-fed rats.

2757 LIVER CELLS IN SUSPENSION SYNTHESIZE BUT DO NOT SECRETE THE NEWLY SYNTHESIZED SERUM ALBUMIN. *(E.)*

Hussain, L. F.; Bhargava, P. M. (Regional Res. Lab., Hyderabad, India). *Arch. Biochem. Biophys.* 161(1):153-160, 1974.

Liver cells from inbred albino rats were prepared in suspension using a mechanical dispersion method. The cells incorporated labeled amino acids into serum albumin at a rate comparable to that observed in slices from unperfused and citrate-perfused liver over a 2-hr period. However, while the slices secrete about 89% of the newly synthesized albumin into the medium, the cell suspension secrete only 9%. This blockage affects only the secretion of albumin which is synthesized after dispersion of the tissue and does not extend equally to albumin synthesized prior to dispersion of the tissue to a single cell suspension or to other proteins synthesized in the cell suspensions. The reason for the loss in the ability of the liver cell suspensions to secrete the newly synthesized albumin is unknown.

2758 HEPATOCYTE PROLIFERATION AND α_1-FETOPROTEIN IN PREGNANT, NEONATAL, AND PARTIALLY HEPATECTOMIZED RATS. *(E.)*

Sell, S.; Nichols, M.; Becker, F. F.; Leffert, H. L. (Univ. California at San Diego Med. Sch., La Jolla). *Cancer Res.* 34(4): 865-871, 1974.

Serum α_1-fetoprotein concentrations were monitored in pregnant rats from conception through delivery and during the following 3-4 weeks postpartum and in the sera of neonatal rats from birth through maturity. The kinetic changes in the α_1-fetoprotein concentrations of partially hepatectomized rats were also monitored and the proportions of DNA-synthesizing hepatocytes in newborn and regenerating livers were correlated with serum α_1-fetoprotein concentrations. Increasing α_1-fetoprotein concentrations follow rounds of hepatocellular proliferation, indicating that the production of α_1-fetoprotein is closely coupled to cellular division. Thus, α_1-fetoprotein is either synthesized transiently and released by a postmitotic cell or it is synthesized prior to mitosis and released after mitosis. There is also evidence that proliferation is not absolutely necessary for α_1-fetoprotein production to occur.

2759 GLUCAGON CONTROL OF CYCLIC AMP ACCUMULATION IN ISOLATED INTACT RAT LIVER PARENCHYMAL CELLS *IN VITRO*. *(E.)*

Christoffersen, T.; Berg, T. (Inst. Pharmacol., Univ., Oslo, Norway). *Biochim. Biophys. Acta* 338(2):408-417, 1974.

Cyclic AMP levels were measured in suspensions of isolated Wistar rat liver parenchymal cells during *in vitro* incubation. Glucagon caused a rapid elevation in the cyclic AMP content. With 1.4×10^{-6} M (5 μg/ml) of the hormone, the levels increased about 10-fold during the first minute, after which the elevation rate was less rapid. Maximal values were reached after 5-10 min. Theophylline (2 or 5 mM) slightly increased the basal cyclic AMP levels and markedly augmented the response to glucagon. The major portion of the cyclic AMP was located within the cells, but a significant fraction was present in the incubation medium, and the relative amount present extracellularly increased with incubation time. Significant elevation of the cyclic AMP levels was produced by glucagon in concentrations greater than or equal to 1.4×10^{-10} M, and half-maximal stimulation occurred at about 2×10^{-9} M. The initial rate of cyclic AMP accumulation was much more rapid in the parenchymal cells than in slices of liver, and the maximal levels obtained were about 3 times higher. Preparations of parenchymal liver cells are useful in studying the actions of glucagon on liver tissue.

2760 LIVER INJURY FOLLOWING HALOTHANE ANESTHESIA IN PHENOBARBITAL-PRETREATED RATS. *(E.)*

Reynolds, E. S.; Moslen, M. T. (Peter Brigham Hosp., Boston, Mass.). *Biochem. Pharmacol.* 23(2):189-195, 1974.

Linear foci of centrolobular necrosis on the posterior aspect of the liver were consistently produced by 5 hr of anesthesia with 0·85% halothane in young male Charles River rats pretreated with phenobarbital (1 g/liter drinking water) for 30 days. Microsomes isolated from livers of these animals immediately upon completion of anesthesia had elevated lipid-conjugated diene and decreased cytochrome P-450 content and ^{14}C-glycine incorporation into protein *in vivo*. Lipid-conjugated dienes and glycine incorporation, but not P-450, returned to pre-anesthesia levels within 2 hr. None of these alterations was evident after anesthesia in livers of saline-pretreated rats (0·23 g NaCl/liter drinking water). Aside from the persistence of decreased P-450 in phenobarbital-pretreated animals, alterations in lipid-conjugated diene and glycine incorporation did not occur after repeated anesthesia at 48-hr intervals, nor was hepatic necrosis as evident, although anesthesia recovery times increased significantly. These findings indicate that metabolites of halothane are

rectly hepatotoxic and that repeated anesthesia
th halothane at 2-day intervals decreases its
epatotoxic effect, presumably by interfering with
s metabolism to toxic metabolites by the endoplas-
c reticulum. Similar morphologic lesions can also
 produced in phenobarbital-pretreated animals by
inute doses of CCl_4.

761 AUTOREGULATION OF GLYCOLYSIS, RESPIRATION,
GLUCONEOGENESIS AND GLYCOGEN SYNTHESIS IN
OLATED PARENCHYMAL RAT LIVER CELLS UNDER AEROBIC
D ANAEROBIC CONDITIONS. *(E.)* Seglen, P. O. (Nor-
gian Radium Hosp., Oslo). *Biochim. Biophys. Acta*
8(2):317-336, 1974.

renchymal cells isolated from the livers of male
star rats fasted for 16 hr have a comparatively
w ability to utilize glucose, although fructose
 utilized very effectively by these cells. Gluco-
ogenesis from lactate, pyruvate, or fructose is
t subject to end-product inhibition by glucose
 physiological concentrations (5-20 mM) in cells
om fasted rats. However, glucose has a stimula-
ry and probably direct effect on glycogen synthe-
s. Liver cells from rats starved for 40 hr have
rgely lost the ability to synthesize glycogen.
ycolysis from fructose is strongly inhibited by
e end-product lactate under aerobic conditions.
ctate, but not pyruvate, slightly inhibits glyco-
n synthesis from high concentrations of fructose,
ile quinolinate, which blocks gluconeogenesis from
ctate (but not from fructose), does not prevent
e lactate inhibition of glycogen synthesis. Un-
r anaerobic conditions, glycolysis from fructose
 strongly stimulated, whereas gluconeogenesis and
ycogen synthesis are blocked. The end-product
hibition of glycolysis by lactate also largely
isappears during anaerobiosis. The concept of a
eneralized Pasteur effect" is introduced to empha-
ize the multiplicity of oxygen effects on liver
rbohydrate metabolism.

762 INFLUENCE OF DIETARY BILE ACIDS ON FORMA-
TION OF BILE ACIDS IN RAT. *(E.)* Daniels-
n, H. (Karolinska Inst., Stockholm, Sweden).
teroids 22(5):667-675, 1973.

ale Sprague-Dawley rats received various taurine-
njugated bile acids at the 1%-level in the diet for
 or 7 days. The effect on several hydroxylations
nvolved in the biosynthesis and metabolism of bile
cids was studied. The 7α-hydroxylation of choles-
erol was inhibited by feeding taurocholic acid,
aurochenodeoxycholic acid and taurodeoxycholic acid
or 3 or 7 days. Taurohyodeoxycholic acid or
aurolithocholic acid caused no marked inhibition.
he 12α-hydroxylation of 7α-hydroxy-4-cholesten-3-
ne was inhibited after 3 or 7 days by all bile acids
xcept taurohyodeoxycholic acid. This acid caused a
arked stimulation of 12α-hydroxylation. The effects
f the different bile acids on the 7α-hydroxylation
f taurodeoxycholic acid were not great. Taurocholic
cid and taurodeoxycholic acid stimulated the 6β-
ydroxylation of lithocholic acid and taurochenodeoxy-
holic acid. The reaction was inhibited by tauro-
henodeoxycholic acid, at least after 7 days. Taurohyodeoxycholic acid inhibited the 6β-hydroxylation slightly. Taurolithocholic acid had no effect. The finding that taurohyodeoxycholic acid and taurolithocholic acid have no effect on cholesterol 7α-hydroxylase suggests that bile acids may have to fulfill certain structural requirements to be able to inhibit bile acid biosynthesis. The lack of effect of taurohyodeoxycholic acid on cholesterol 7α-hydroxylase and the stimulatory effect on 7α-hydroxy-4-cholesten-3-one 12α-hydroxylase appear to contradict earlier findings which indicate that feeding of hyodeoxycholic acid results in an overall stimulation of cholesterol excretion. The effects on 6β-hydroxylation of lithocholic acid and on 6β-hydroxylation of taurochenodeoxycholic acid were the same, indicating the same enzyme system catalyzes both reactions.

2763 THE CHOLERETIC EFFECT OF PURE NATURAL CHOLECYSTOKININ IN DOGS. *(E.)* Thulin, L. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 139(7):635-640, 1973.

The hepatic bile flow was studied in 4 dogs with permanent bile fistulas which functioned during 5-21 weeks. The experiments were performed in animals which had fasted for 16-22 hr. After a 2 hr control period the bile flow was studied under various experimental conditions. In one group fasting was continued for another 6 hr (4 experiments in 2 dogs) and the bile flow remained at the control values. In a second group dogs received orally a standard meal of food alone (6 experiments in 3 dogs), the bile produced during the previous 24 hr (2 experiments in 1 dog), or food together with bile (5 experiments in 3 dogs). After food alone, the bile flow increased to 117-212%; after bile, to 580-740%; and after food with bile, to 405-675% of control values. In a third group dogs were given 2 hr infusions of pure natural cholecystokinin, (0.25-32 Ivy dog units/kg/hr, i.v.) for 40 experiments in 4 dogs. A dose-response curve in 3 dogs showed a threshold effect on the bile flow at 2-4 units/kg/hr and a maximum stimulation at 8 units/kg/hr. No further effect was observed at higher dosages. The average maximum bile flow in 4 dogs was approximately 250% of the control values. The cholecystokinin effect on the bile flow was quantitatively comparable to the effect of feeding with food alone, but lower than the effect of bile alone or food with bile.

2764 ACTIVATION OF HEPATIC MICROSOMAL GLUCURONYL TRANSFERASE BY BILIRUBIN. *(E.)* Sanchez, E.; Tephly, T. R. (Toxicol. Ctr., Univ. Iowa, Iowa City). *Life Sci.* 13(11):1483-1490, 1973.

In liver microsomal preparations from Sprague-Dawley rats, bilirubin, in concentrations of 0.1 to 2.0mM, markedly stimulated the glucuronidation of morphine and p-nitrophenol catalyzed by UDPglucuronyltransferase. The activation was not due to contamination of bilirubin with bile acids. At equimolar concentrations, the activating effect of bilirubin was greater than that produced by deoxycholate, a detergent well known as an activator of UDPglucuronyltransferase. Other results suggest that bilirubin activation of UDPglucuronyltransferase is similar to that produced by detergents. *In vivo* experiments showed that the rate of urinary excretion of morphine glucuronide in rats treated with bilirubin was twice that of control animals. These results indicate that, beyond a critical concentration of detergent, bilirubin can only inhibit UDPglucuronyltransferase activity toward p-nitrophenol. It is suggested that bilirubin may be a physiologic activator of UDPglucuronyltransferase activity.

2765 EFFECT OF CHRONIC ETHANOL TREATMENT ON TRYPTOPHAN OXYGENASE, TYROSINE AMINOTRANSFERASE AND GENERAL PROTEIN METABOLISM IN THE INTACT AND PERFUSED RAT LIVER.

(E.) Morland, J. (Dept. Pharmacol., Univ. Oslo, Norway). *Biochem. Pharmacol.* 23(1):21-35, 1974.

Male Wistar rats (275-300 g body wt) were given ethanol to provide 31 per cent of the total calories while sucrose replaced ethanol isocalorically in controls. Thirty-six per cent of the calories were provided by fat in both groups. Tryptophan oxygenase activity was reduced to about 60% of control activity in livers from rats treated with ethanol for 38 days. This effect was not a consequence of a reduction of *in vivo* corticosterone levels in the treated animals. Tyrosine aminotransferase activity was unchanged in these livers. When the livers were perfused with dexamethasone (20 μg/ml), the induction of both enzymes was significantly lower in ethanol-treated rats. The incorporation of labelled amino acids into protein 30 and 45 min after the addition of label was also reduced in livers from treated rats. The degradation of tryptophan oxygenase, tyrosine aminotransferase, and general proteins, measured in perfused liver after cycloheximide (50 μg/ml) was not significantly affected by previous ethanol consumption. No obvious leakage of liver proteins to the perfusate could be registered after ethanol treatment. Ethanol treatment did not significantly influence plasma bilirubin, liver bile production, liver lipids or gross histological appearance of the liver. It was concluded that liver tryptophan oxygenase, tyrosine aminotransferase and general protein synthesis was reduced as a consequence of the previous chronic intake of ethanol independent of changes in the other liver parameters measured.

2766 EFFECT OF ETHANOL ON LIVER TRIGLYCERIDE CONCENTRATION IN FED AND FASTED RATS.

(E.) Johnson, O. (Dept. Chem., Univ. Umea, Sweden). *Lipids* 9(1):57-60, 1974.

The effect of ethanol, given by gastric tube or by intraperitoneal injection, on the liver triglyceride concentration in fasted and *ad libitum* fed female Sprague-Dawley rats was investigated. Ethanol, independent of the route of administration, increased the liver triglyceride concentration in fasted rats during an 8 hr period but caused a much smaller increase in the *ad libitum* fed rats. The incorporation of intravenous injected ^{3}H-oleic acid into the liver triglycerides increased significantly after ethanol feeding in fasted but not in fed rats. Based upon this and the plasma free fatty acid concentrations, it is concluded that ethanol causes a marked increase in the utilization of plasma free fatty acids for synthesis of liver triglycerides in fasted but not in fed rats. It is suggested that this is part of the explanation for the different responses to ethanol of the liver triglyceride concentrations in fasted and fed rats.

2767 THE COMBINED EFFECT OF ETHANOL AND PHENOBARBITAL ON THE ACTIVITIES OF HEPATIC DRUG METABOLIZING ENZYMES IN RATS.

(E.) Luoma, P.; Vorme, M. (Univ. of Oulu, Finland). *Acta Pharmacol. Toxicol.* 33(5-6):442-448, 1973.

The effect of feeding ethanol (15% v/v) and/or phenobarbital (0.05% w/v) in drinking water on the rate of metabolism of methylaniline and *p*-nitrobenzoic acid, and on the microsomal protein and the cytochrome P-450 contents in the liver of male Sprague-Dawley rats was studied. Animals treated with ethanol for 3 days showed an increase in N-demethylation of methylaniline of 88%, whereas the nitroreduction of *p*-nitrobenzoic acid was inhibited by 47%. Ethanol and phenobarbital had a synergistic action on N-demethylation. Ethanol inhibited the induction of nitroreduction by phenobarbital. Ethanol, like phenobarbital, increased microsomal protein and they acted synergistically in this respect. Ethanol, like phenobarbital, caused a significantly greater increase in microsomal cytochrome P-450 than in microsomal protein content, and they also acted synergistically on cytochrome P-450. The effects of ethanol on the N-demethylase activity, cytochrome P-450 and microsomal protein are presumably associated with the increase in the smooth endoplasmic reticulum as also occurs with phenobarbital and other inducers. The rates of synthesis of individual proteins associated with the endoplasmic reticulum can vary independently, either increasing or decreasing, and this may explain the different actions of ethanol and phenobarbital on the enzyme activities studied.

2768 METABOLISM OF MONO- AND DIHYDROXYLATED BILE ACIDS IN PREPARATIONS OF HUMAN LIVER.

(E.) Bjorkhem, I.; Einarsson, K.; Hellers, G. (Karolinska Inst., Stockholm, Sweden). *Eur. J. Clin. Invest.* 3(6):459-465, 1973.

The metabolism of tritium-labelled taurodeoxycholic acid, taurochenodeoxycholic acid, taurolithocholic acid and of [24-^{14}C]lithocholic acid and [24-^{14}C]3-keto-5β-cholanoic acid was studied in fractions of human liver homogenates. In the presence of microsomal fraction fortified with an NADPH-generating system a small conversion of taurodeoxycholic acid into taurocholic acid occurred. No significant hydroxylation of taurochenodeoxycholic acid, taurolithocholic acid or free lithocholic acid could be detected. In the presence of microsomal fraction fortified with NAD lithocholic acid was converted into 3-keto-5β-cholanoic acid. In the presence of microsomal fraction fortified with NADH, 3-keto-5β-cholanoic acid was reduced to isolithocholic acid and lithocholic acid (ratio 3:1). In the presence of 100,000 x *g* supernatant fraction only lithocholic

id was formed from 3-keto-5β-cholanoic acid. The
patic conversion of lithocholic acid into isolitho-
olic acid may have some physiological significance
nce isolithocholic acid and lithocholic acid prob-
ly differ in their toxic properties. Thus, 3β-
droxy steroids are in general less hemolytic than
-hydroxy-steroids and it has been reported that
olithocholic acid is less pyrogenic than litho-
olic acid.

'69 STUDIES OF THE HEPATIC EXCRETORY DEFECTS
IN ESSENTIAL FATTY ACID DEFICIENCY: THEIR
SSIBLE RELATIONSHIP TO THE GENESIS OF CHOLESTEROL
LLSTONES. *(E.)* Sarfeh, I. J.; Beeler, D. A.;
eble, D. H.; Balint, J. A. (Albany Med. Col. Union
iv., N.Y.). *J. Clin. Invest.* 53(2):423-430, 1974.

le hamsters were fed normal and essential fatty
id deficient diets for at least 12 weeks before
le duct cannulation. With [^{32}P]phosphate, hepa-
c synthesis of lecithin was similar, but biliary
cretion of newly synthesized lecithin was signifi-
ntly reduced in essential fatty acid-deficient ham-
ters compared to that in normal hamsters. Hepatic up-
ke of intravenously infused taurocholate and tauro-
enodeoxycholate were similar in both groups of ani-
als. However, biliary excretion of intravenously in-
sed taurocholate was significantly reduced in essen-
ial fatty acid-deficient hamsters, whereas that of
urochenodeoxycholate was unchanged. The absolute
te of biliary cholesterol excretion was similar in
th groups. Canalicular bile flow, as measured by
^{14}C]erythritol clearance after functional nephrec-
my, was significantly lower, with both the bile
lt-dependent and independent fractions of this
ow being diminished in essential fatty acid-defi-
ent hamsters infused with taurocholate. It is
ncluded that essential fatty acid deficiency leads
impaired biliary excretion of taurocholate, leci-
in, and water, while cholesterol transport is un-
fected, and thus results in supersaturation of bile
th respect to cholesterol and production of litho-
nic bile.

70 THE EFFECT OF SIMULATED METABOLIC ACIDOSIS
ON INTRACELLULAR pH AND LACTATE METABOLISM
THE ISOLATED PERFUSED RAT LIVER. *(E.)* Lloyd, M.
; Iles, R. A.; Simpson, B. R.; Strunin, J. M.;
ayton, J. M.; Cohen, R. D. (London Hosp. Med. Coll.,
ngland). *Clin. Sci. Mol. Med.* 45(4):543-549, 1973.

e effect of changes in extracellular pH (pH_e) and
tracellular pH (pH_i) on lactate uptake was studied
the isolated liver of Wistar rats. The mean lac-
ate concentrations in the perfusate at the time of
H_i measurement were 2.13, 2.02, 2.19, 2.36, and
.98 mmol/l for the experiments in which pH_i lay
ithin the ranges 7.4-7.2, 7.2-7.1, 7.1-7.0, 7.0-6.9,
nd 6.9-6.8, respectively. None of these mean
alues differed significantly from each other. As
H_e decreased from 7.4 to 6.85, mean pH_i fell rela-
ively little. Further lowering of pH_e from 6.85
o 6.7 resulted in almost as great a fall of mean
H_i. Mean lactate uptake was between 0.9 and 2
mol min^{-1} 100 g rat^{-1} when pH_e lay between 7.4 and
.1. Lower values of pH_e were associated with progressively lower lactate uptakes and when pH_e fell below 7.1-7.0, mean lactate uptake was negative, although the mean value of the lactate outputs for the 2 groups of perfusions with the 2 lowest pH_e levels were not significantly less than zero when combined. Mean lactate uptake did not vary appreciably over the pH_i range 7.4-7.0. At lower levels of pH_i an abrupt change over from uptake to output of lactate occurred. The results show that there is little effect on lactate uptake as pH_i is decreased to 7.1; thereafter a rapid fall in lactate uptake occurs and pH_i values below 7.0, lactate output occurs. The relationship between pH_e and lactate uptake is somewhat similar to that between pH_i and lactate uptake. The effect of metabolic acidosis in converting hepatic lactate uptake to output could be relevant to clinical lactic acidosis, whether due to poor tissue perfusion or to other mechanisms. It is possible that the success of therapeutic measures in either type of lactic acidosis may be dependent on raising hepatic intracellular pH.

2771 BIOCHEMICAL ASPECTS OF EXPERIMENTAL HEPATIC ALLOTRANSPLANTATION. *(E.)* Halliday, J. P.; Sheil, A. G. R.; Hensley, W. J.; Bookallil, M. J.; Wotherspoon, G. P. (Dept. Surg., Univ. Sydney, Australia). *Arch. Surg.* 108(1):75-80, 1974.

Hepatic allografts were performed in 14 pigs using techniques designed to minimize damage to the allograft. Ten of these transplants were successful, with failure in the remaining 4 cases being due to technical problems. All allografts undergoing successful revascularization secreted bile freely and hemorrhagic diathesis did not occur. All survivors recovered vigorously; in none was the serum bilirubin level elevated in the early postoperative period, nor were serum glucose levels difficult to maintain. In all surviving animals, the serum enzyme levels returned to normal early in the first postoperative week. With regard to the donor livers, hepatocellular damage reflected by elevated SGOT levels became evident during perfusion and developed slowly after revascularization. Similar changes in lactic dehydrogenase were not found. Potassium efflux during cold perfusion appeared to be related to reversible changes in membrane potential and enzyme activity induced by hypothermia, not to damage. Interference with the hepatic synthesis of plasma proteins and cholesterol was observed. The depression in cholesterol synthesis was shorter lived than the depression in plasma protein synthesis.

2772 NUTRITIONAL REGULATION OF LIPID METABOLISM IN RATS. IV. METABOLISM OF HEPATIC GLYCEROLIPIDS IN FASTED RATS *IN VIVO* AND *IN VITRO*. *(E.)* Imaizumi, K.; Yamamoto, M.; Sugano, M. (Fac. Agric., Kyushu Univ., Japan). *J. Nutr. Sci. Vitaminol.* 19(5):419-431, 1973.

^{14}C-palmitate and linoleate were injected i.p. into male Wistar rats which had been fasted for 15 hr; their incorporation into hepatic glycerolipids 0.5 and 6 hr after their injection was markedly depressed. There was no significant reduction in the incorporation of ^{14}C-stearate. The fractional disappearance rate of ^{14}C-linoleate from phosphatidylcholine (PC) and phosphatidylethanolamine was increased in the fasted rats, as was the disappearance rate of ^{14}C-palmitate and stearate into molecorporation of C-palmitate and stearate into molecular PC was specifically altered. Desaturation of these precursors in the liver was depressed by fasting, as was the synthesis of the acyl moieties from acetate. When ^{14}C-acetate was injected i.p. at the beginning of fasting, the turnover of the labeled fatty acids in the liver between 3 and 6 hr postinjection was slower in the fasted rats, the turnover of the polyunsaturated acids being the slowest. The results indicate that the specific changes in the turnover of individual fatty acids in the hepatic glycerolipids are principal determinants of the fasting-induced changes in the fatty acid composition.

2773 A MECHANISM OF THE ACCELERATION OF LIPID PEROXIDE FORMATION IN LIVER HOMOGENATES AND SUBCELLULAR FRACTIONS OF VITAMIN E-DEFICIENT MICE. *(E.)* Fukuzawa, K.; Uchiyama, M. (Fac. Pharm., Univ. Tokushima, Japan). *J. Nutr. Sci. Vitaminol.* 19(5):433-453, 1973.

Male ddY mice were maintained on normal or vitamin E deficient diets, after which tissue homogenates were prepared from their livers. The concentration of tocopherol was significantly reduced in the livers of the E-deficient animals. There were no significant differences in the hepatic phospholipid contents of the two groups, while in the vitamin E-deficient group the oleic acid level was elevated and the linoleic acid was decreased. The free fatty acid levels were increased in the livers of the vitamin E-deficient mice, although these free fatty acids did not appear to accelerate lipid peroxidation. Lipid peroxidation was unchanged in the presence of Triton X-100 and accelerated in the presence of deoxycholate, Tween 60, and Tween 80. Lipid peroxidation in both normal and vitamin E-deficient liver was promoted with increasing homogenate concentrations. The rate of peroxidation was unaffected by reduced nicotinamide adenine dinucleotide phosphate, increased by reduced nicotinamide adenine dinucleotide phosphate, and inhibited by glutathione; the effects did not differ between the normal and vitamin E-deficient livers. Ascorbate had little effect on lipid peroxidation in the normal or vitamin E-deficient homogenates, but it greatly increased Tween 80 induced peroxidation. Both aminopyrine oxidation and lipid peroxidation were increased in liver homogenates from normal mice pretreated with phenobarbital. In the vitamin E-deficient homogenates, lipid peroxidation was increased and aminopyrine oxidation was decreased by phenobarbital pretreatment. The data suggest that vitamin E exerts its antioxidant effect by preserving the normal structure of the membrane.

2774 GIANT MITOCHONDRIA. II. INDUCTION OF MATRIX ENRICHED MEGAMITOCHONDRIA IN MOUSE LIVER PARENCHYMAL CELLS BY ETHIDIUM BROMIDE. *(E.)* Albring, M.; Radsak, K.; Thoenes, W. (Inst. Cytobiol. Cytopathol., Univ. Marburg, Germany). *Virchows Arch.* [*Zellpathol.*] 14(4):373-377, 1973.

The effects of ethidium bromide on mitochondrial ulstrastructure were studied in livers from weanling male NMRI mice. Each mouse received a single i.p. injection of ethidium bromide (dissolved in saline, 50 μg/g body weight). After 5 days, a randomly chosen number of animals was sacrificed and specimens of liver removed for electron microscopy. All hepatocytes selected from peripheral or intermediate areas of the liver contained distinctly enlarged mitochondria sometimes encroaching the cell nucleus in diameter. In addition, organelles of normal as well as intermediate size could be observed in every cell examined. Mitochondrial enlargement was, however, less pronounced in central parts of the lobule showing only a moderate degree of mitochondrial structural alteration. Giant mitochondria were characterized by a vastly augmented matrix, which was constant in electron density, regardless of the size of the single mitochondrion. It is concluded that the induction of megamitochondria by ethidium bromide supports the concept of mitochondrial fusion as the originally underlying process.

2775 INFLUENCE OF ALBUMIN ON THE HEPATIC UPTAKE OF UNCONJUGATED BILIRUBIN. *(E.)* Bloomer, J. R.; Berk, P. D.; Vergalla, J.; Berlin, N. I. (Natl. Cancer Inst., Bethesda, Md.). *Clin. Sci. Mol. Med.* 45(4):505-516, 1973.

The influence of albumin on the hepatic uptake of unconjugated bilirubin was studied. The initial distribution volumes of [^{3}H]bilirubin in 6 adult subjects were equivalent to those of ^{131}I-labelled albumin following simultaneous intravenous injection of both compounds. However, the initial rate of loss of [^{3}H]bilirubin from plasma was 7 to 30 times faster than that of ^{131}I-labelled albumin. *In vitro* uptake of [^{3}H]bilirubin by Gunn rat liver slices occurred at a rate 3 times faster than could be accounted for by movement linked with albumin. There was no *in vitro* transfer of [^{14}C]bilirubin from albumin to the organic anion-binding proteins of rat liver cytosol. Instead, albumin was shown to strip [^{14}C]bilirubin from these proteins. When albumin, to which [^{14}C]bilirubin had been bound, was precipitated with anti-albumin antibody, [^{14}C]bilirubin was recovered completely in the supernatant, indicating that unconjugated bilirubin may be readily separated from albumin if albumin interacts with another macromolecule. These results indicated that unconjugated bilirubin is separated from albumin prior to its uptake by the hepatic cell, rather than the entire albumin-bilirubin complex entering the hepatocyte. The data suggest that the uptake mechanism probably requires the participation of the plasma membrane.

2776 SYNTHESIS OF ESSENTIAL AMINO ACIDS FROM THEIR α-KETO ANALOGUES BY PERFUSED RAT LIVER AND MUSCLE. *(E.)* Walser, M.; Lund, P.; Ruderman, N. B.; Coulter, A. W. (Nuffield Dept. Med., Oxford Univ., England). *J. Clin. Invest.* 52(11):2865-2877, 1973.

Isolated rat liver and hindquarter (muscle) preparations from female Wistar rats were perfused with keto-analogues of valine, leucine, isoleucine, meth-

onine, or phenylalanine to determine the fate of
ese α-keto-analogues in tissues of normal animals.
en perfused at 1.5-2.0 mM, all 5 compounds were
ilized rapidly by the liver of 48-hr starved rats,
: rates varying from 49 to 155 μmol/hr/200 g rat.
e corresponding amino acids appeared in the medium
i significantly increased concentrations. Perfusion
th phenylpyruvate also led to the appearance of
rosine. Urea release was unaltered. Measurement
f metabolite concentrations particularly at keto-
cid concentrations of 5 mM or above in freeze-
lamped liver revealed a large increase in α-
etoglutarate, and a moderate to marked decrease in
issue glutamine. This decrease was quantitatively
ufficient to account for nitrogen appearing in newly
ynthesized amino acids. Isolated hindquarters of
ed rats were perfused with the same ketoacids at
oncentrations of 1.3-8.0 mM. All were utilized at
ates varying from 1.4 to 7.0 μmol/hr/g muscle per-
used. The correspondong amino acids were released
: greatly increased rates. Alanine and glutamate
evels fell in some perfusions, but the principal
itrogen donor in muscle was not identified; the
ontent of glutamine in tissue, and its rate of re-
ease into the perfusate remained constant. It is
uggested that diseases characterized by abnormal
ccumulations of the ketoacids studied here may also
xhibit some of the secondary metabolic disturbances
bserved in the perfused liver.

777 EFFECT OF TRANSIENT BILIARY OBSTRUCTION ON LIVER FUNCTION AND MORPHOLOGY. *(E.)* So,
. U.; Bondar, G. F. (Surg.-Med. Res. Inst., Univ.
lberta, Edmonton, Canada). *Can. J. Surg.* 17(1):
9-58, 1974.

artial biliary obstruction was produced in 80 guinea
igs by partial ligation of the distal common bile
uct and maintained from 4 to 8 weeks. Partial
iliary obstruction up to 8 weeks produced marked
epatic changes. The significant functional changes
ere elevations of the serum alkaline phosphatase
nd SGOT levels (37.2 Babson U and 44.7 TransAc U,
esp., at 8 weeks) and decrease of the serum albumin
evels (0.83 g/100 ml). Morphologically, the promi-
ent changes were round cell infiltration, fibrosis,
nd bile duct proliferation with dilatation in the
ortal and interlobular areas, parenchymal cell
trophy and focal necrosis. Peak elevations of in-
raductal pressure after 4 and 8 weeks were noted at
imes when significant morphological changes occurred
n the liver. Surgical relief of obstruction resul-
ed in rapid recovery of liver function and restor-
tion of normal morphology after 8- and 20-week peri-
ds. Therefore, partial biliary obstruction of up
o 8 weeks is reversible in the guinea pig.

778 ORTHOPHOSPHATE CONVERSION IN CCl_4-DAMAGED LIVER. *(Ger.)* Fleischer, I.;

SECRETION AND METABOLISM

Intestine

56 THE EFFECT OF INDOMETHACIN ON THE RELEASE OF PROSTAGLANDIN E_2 AND ACETYLCHOLINE OM GUINEA-PIG ISOLATED ILEUM AT REST AND DURING ELD STIMULATION. *(E.)* Botting, J. H.; Salzmann, (Dept. Pharmacol. Univ. London, England). *. J. Pharmacol.* 50(1):119-124, 1974.

inea-pig ileum suspended in Krebs solution showed continuous increase of tone which was lost by anging the bath fluid. Prostaglandin E_2 was re- ased from the ileum during incubation, and its con- ntration in the bath fluid appeared to correlate th the increase in tone. Supramaximal field sti- lation (10 Hz) resulted in increased release prostaglandin E_2 from the ileum. At lower rates stimulation, the increase in the release of E_2 compared with the resting output was not significant. Indomethacin (1 and 10 μg/ml) produced a significant, dose-related reduction of the amount of prostaglandin E measured in the bath fluid at rest and with field stimulation. Indomethacin inhibited the contraction of the ileum during incubation in Krebs solution. Indomethacin (10 and 20 μg/ml) had no significant effect on the release of acetylcholine during field stimulation, but reduced the resting output of acetylcholine from guinea-pig ileum in some experiments. Prostaglandins are assumed to be physiological modulators in the release of transmitter in the adrenergic nervous system, and a similar feed-back mechanism has been suggested for the parasympathetic nervous system. If this type of feed-back mechanism actually existed in the parasympathetic nervous system, inhibition of prostaglandin synthesis by indomethacin should have increased acetylcholine release in the guinea-pig isolated ileum. Thus no evidence was obtained of a prostaglandin-mediated negative feedback mechanism affecting acetylcholine release.

2857 SMALL INTESTINAL PHLORIZIN HYDROLASE: THE "β-GLYCOSIDASE COMPLEX." *(E.)*

Colombo, V.; Lorenz-Meyer, H.; Semenza, G. (Dept. Biochem. Swiss Inst. Technol., Zurich). *Biochim. Biophys. Acta* 327(2):412-424, 1973.

The age dependence and association with neutral lactase of phlorizin hydrolase activity were studied. Phlorizin hydrolase activity in rat small intestine is highest at birth and decreases at the time of weaning, reaching the low adult level at about 20 days of age. This age dependence is very similar to that of small intestinal lactase, and is quite different from that of the small intestinal β-glucosidases (maltase, sucrase, isomaltase, and trehalase) which are essentially absent at birth and begin to develop between 15 and 16 days of life. The similar age dependence of lactase and phlorizin hydrolase, together with a strong correlation between these 2 activities in a random sample of human peroral biopsies and the absence of phlorizin hydrolase activity in the small intestine of patients affected by lactase deficiency indicate that phlorizin hydrolase and lactase activities are either due to the same catalytic site, or, if due to more than one enzyme, that they are subjected to similar or related biological control mechanisms. Neutral (brush-border bound) lactase was isolated from the small intestine of baby rats. The lactase/phlorizin hydrolase ratio remains essentially constant during those fractionation steps which bring about an almost 70-fold purification. The different time-course of heat inactivation of the 2 glycosidase activity in essentially pure rat intestinal lactase, in partially purified hamster intestinal lactase, and in total homogenate of human small intestine shows that in these species the 2 glycosides are not split by a single common catalytic site. Lactase and phlorizin hydrolase activities are due to the same protein or protein complex (referred to as the "β-glycosidases complex"); however, they are due to at least 2 independent or partially independent catalytic sites. The hydrolysis of a number of hetero-β-glycosides was examined by a partially purified preparation of hamster lactase-phlorizin hydrolase, before and after partial heat denaturation. Meta and p-nitro-phenyl-β-glucosidase activities survive the treatment essentially to the same extent as phlorizin hydrolase activity, making them suitable substrates for a further study. The β-glucosides compete mutually for the same catalytic site and the contribution of the lactase moiety for m-nitrophenyl-β-glucosidase activity must be minimal or zero. Phlorizin inhibits sugar uptake (uptake of 6-deoxy-D glucose) in the small intestine of baby rats more than in adult rats.

2858 ACTIVE ELECTROLYTE SECRETION STIMULATED BY CHOLERAGEN IN RABBIT ILEUM *IN VITRO.*

(E.) Powell, D. W.; Binder, H. J.; Curran, P. F. (Yale Univ. Sch. of Med., New Haven, Conn.). *Am. J. Physiol.* 225(4):781-787, 1973.

Purified cholera toxin added to the mucosal solution of New Zealand rabbit ileum *in vitro* caused changes in ion fluxes and electrical properties after a 50- to 60-min lag period. Potential difference and short-circuit current increased and tissue conductance decreased. In Ringer solution containing HCO_3, the toxin caused net secretion of both Na and Cl. In HCO_3-free solution, the toxin reduced net Na transport to zero and caused Cl secretion. No effects of toxin were observed on Na fluxes in HCO_3-Cl-free solution or on Cl fluxes in Na-free solution. The changes in net electrolyte fluxes are most easily explained by postulating that cholera toxin stimulates an electrically neutral process that transports NaCl and/or $NaCHO_3$ from serosa to mucosa.

2859 SYNTHESIS OF INTESTINAL GLYCOPROTEINS. INHIBITIONS OF 1-^{14}C GLUCOSAMINE INCORPORATION BY PHENYLBUTAZONE IN VIVO. *(E.)*

Lukie, B. E.; Forstner, G. G. (Dept. Med., Univ. Saskatchewan, Saskatoon, Canada). *Biochim. Biophys. Acta* 338(2): 345-351, 1974.

Phenylbutazone (5 mM) in the presence of sodium taurocholate (10 mM) inhibited incorporation of [1-^{14}C]glucosamine and [^{14}C]leucine into acid-precipitable protein by rat intestinal slices. Inhibition of [1-^{14}C]glucosamine incorporation was independent of medium glucosamine concentration. Phenylbutazone inhibited [1-^{14}C]glucosamine incorporation by cycloheximide-treated slices. Reduced [1-^{14}C]glucosamine incorporation did not result solely from inhibition of protein synthesis; a specific inhibition of oligosacharide assembly was demonstrated. Analysis of mucosal acid-soluble intermediate labeling revealed an increase in glucosamine and a reduction in all hexosamine intermediates following phenylbutazone. The major block of glucosamine incorporation produced by this agent occurred at the N-acetylation step. These effects closely parallel previous experience with sodium salicylate and may represent a common basis for their adverse gastrointestinal effects.

2860 THE ACTIONS OF PROSTAGLANDINS E_2 AND $F_{2\alpha}$ ON HUMAN FOETAL INTESTINE. *(E.)*

Hart, S. L. (Makerere Univ. Med. Sch., Kampala, Uganda). *Br. J. Pharmacol.* 50(1):159-160, 1974.

The response of human fetal intestinal tissue to prostaglandins E_2 and $F_{2\alpha}$ was investigated. Tissue was taken from the duodenum, ileum, distal ileum, ascending, transverse, or descending colon, and was allowed to equilibrate for 2 hr before the administration of drugs. Each tissue was shown to be capable of responding to acetylcholine and to noradrenaline before the actions of the prostaglandins were studied. There were 25 tissues from 8 fetuses, of gestational age 14-26 weeks. that responded to acetylcholine (5-130 ng/ml) and noradrenaline (0.5-10 μg/ml). Two preparations of duodenum, 10 of ileum, and 4 of distal ileum were studied and, on 8 of these, responses to noradrenaline were ob-

ned only in the presence of acetylcholine. An
um preparation from an 18-week fetus, which re-
ed in the presence of noradrenaline alone, gave
iphasic response, consisting of a small relaxa-
n and a much larger contraction, to both pro-
glandin E_2 and $F_{2\alpha}$. All other tissues from
small intestine contracted in the presence of
prostaglandins. The threshold dose of pro-
glandin E was usually 0.1 μg/ml but one ileum
paration, from a 22-week fetus, responded to a
centration of 4 ng/ml. Of 9 tissues from the
ge intestine, only an ascending colon preparation
axed in the presence of noradrenaline alone. Each
sue from the large intestine contracted in the
sence of prostaglandin E but the large intestine
less sensitive than the small intestine. The
ge intestine was also less sensitive to acetyl-
line. The contraction to either prostaglandin
or $F_{2\alpha}$ was unaltered in the presence of a con-
tration of hyoscine (0.6 ng/ml), which produced
e than 50% inhibition of the acetylcholine con-
action. The responses of the small and large in-
stine to both prostaglandin E_2 and $F_{2\alpha}$ were ant-
nized by polyphloretin phosphate at (80-160
/ml). The youngest tissue in this study was from
14-week old fetus and the response of this tissue
prostaglandins demonstrated that prostaglandin
ceptors, as well as muscarinic receptors and
renoceptors, are present at an early stage of
tal development.

61 THE PHOSPHOLIPASE A_2 ACTIVITY OF HUMAN SMALL INTESTINAL CONTENTS. *(E.)* Ihse, I.;
nesjo, B. (Univ. Hosp. Lund, Sweden). *Acta Chem.*
and. 27(8):2749-2756, 1973.

e properties, substrate requirements, kinetics,
d the behavior of small intestinal phospholipase
were studied during gel chromatography. The
ospholipase A_2 activity of small intestinal aspir-
es stored for 3 to 4 weeks at room temperature
s completely stable. Thus the enzyme is protected
ainst proteolytic inactivation in the intestinal
men. Previously filtered intestinal contents were
romatographed on Sephadex G 100 equilibrated and
uted with 0.15 mol/liter NaCl. Phospholipase A
d lipase appeared in the void volume as previously
served for lipase. Trypsin was eluted at a K_{av}
rresponding to its molecular weight. Accordingly
th phospholipase A and lipase have a tendency to
pear in fractions which under such circumstances
ntain the intestinal emulsion phase. Therefore,
e protection of intestinal phospholipase A against
yptic inactivation is independent of phase separa-
on. Intestinal contents centrifuged at 55,000
v for 1 hr exhibited exactly the same phospho-
pase A activity as before centrifugation. An
crease of 22% of the volume under optimal condi-
ons did not change the accuracy of the measure-
nts. After storage, a progressive decrease of the
from 5 was found. No shift in the optimal pH was
monstrated when using different concentrations of
le salt. With the addition of an excess of edetic
id, no phospholipase A activity was found even
th high concentrations of intestinal contents.
increase of the calcium concentration above the
letic acid concentration increased the enzymic activity until an optimum level was reached at a final concentration above 3 mmol/liter $CaCl_2$. In the absence of bile salt, phospholipase A of small intestinal contents was inactive. In the presence of 4.5 mmol/liter $CaCl_2$ and 12.5 mmol/liter sodium taurodeoxycholate and at 60 C, optimal phospholipase A activity of small intestinal contents was obtained at 8 mg lecithin/ml. Higher concentrations of lecithin inhibited the reaction. The enzymic activity increased in an almost linear fashion with increasing temperature of 60 C above which a decreased activity was found.

2862 LOCALIZATION OF FREE AND BOUND SECRETORY COMPONENT IN HUMAN INTESTINAL EPITHELIAL CELLS: A MODEL FOR THE ASSEMBLY OF SECRETORY IgA. *(E.)* Poger, M. E.; Lamm, M. E. (New York Univ. Sch. of Med., N.Y.). *J. Exp. Med.* 139(3):629-642, 1974.

The cytological and histological distribution of free and bound secretory component in human tissues was studied with fluorescent antibodies. Anti-free secretory component stained the cytoplasm of mucosal columnar cells (both crypts and villi) of the small intestine most prominently in the supranuclear Golgi zone. Both anti-α and anti-bound secretory component prominently stained the luminal border of columnar cells in mucosal crypts; no staining of villous epithelial cells was seen. The staining for bound secretory component and α-chains, which sometimes showed linear, radially oriented striations, was identical and had a variable depth measuring from 3-5 μm. The interepithelial cell spaces, which could be identified above the nucleus, consistently did not stain for free or bound secretory component, or α-chains. α-Chains, without secretory component, were prominent in many lamina propria plasma cells, both in villous cores and about crypts. All specimens of colon showed identical staining. Free secretory component was found predominantly in the supranuclear Golgi zone of columnar crypt cells, similar to its location in the small bowel. Secretory IgA, identified by the simultaneous presence of bound secretory component and α-chains, was seen throughout the apical half of the columnar crypt cell cytoplasm in a granular distribution which was most dense at the luminal surface and decreased in density deeper into the cytoplasm. In the gallbladder mucosa, free secretory component was present in the cytoplasm of the columnar surface epithelial cells in a finely granular pattern. Secretory IgA could not be identified. The serous cells of the bronchial and salivary glands consistently stained for secretory component whereas the mucous cells were uniformaly negative. It is concluded that the results favor a model in which secretory IgA is assembled inside epithelial cells from secretory component, which was synthesized in the same cell, and IgA, which enetered the epithelial cell after synthesis in and secretion by a plasma cell.

2863 GLUCOSE METABOLISM IN JEJUNAL MUCOSA OF FED, FASTED, AND STREPTOZOTOCIN-DIABETIC RATS. *(E.)* Anderson, J. W. (VA Hosp., Lexington, Ky.). *Am. J. Physiol.* 226(1):226-229, 1974.

Glycolytic and gluconeogenic enzyme activities and glycolytic rates were measured in the jejunal mucosa of Sprague-Dawley rats. Tissue homogenates have high rates of glycolysis, which may contribute significantly to the energy requirements of jejunal mucosa. In addition, jejunal mucosa has significant activities for several rate-limiting enzymes of gluconeogenesis with the activities of phosphoenolpyruvate carboxykinase, fructose diphosphatase, and glucose-6-phosphatase ranging from 12 to 21% of hepatic activities for these enzymes. Diabetes, induced by streptozotocin (50 or 75 mg/kg i.v.), was associated with significant increase in hexokinase and glucose-6-phosphate dehydrogenase activities in jejunal mucosa; glucose utilization and lactate production/g wet weight were also significantly increased. These increases in glycoltic rates may provide some of the energy required for the increased intestinal transport of carbohydrates and amino acids in diabetic animals. Fasting produced significant decreases in glycolytic enzyme activities and glycolytic rates, whereas the activities of 3 key gluconeogenic enzymes were significantly increased in jejunal mucosa. These observations suggest that fasting increases gluconeogenic rates in jejunal mucosa, whereas diabetes, which did not alter the activities of these 3 gluconeogenic enzymes, does not increase them.

2864 THE FATE OF LABELLED BILE SALTS INTRODUCED INTO THE COLON. *(E.)*

Morris, J. S.; Heaton, K. W. (Bristol Roy. Infirm., England). *Scand. J. Gastroenterol.* 9(1):33-39, 1974.

In 9 subjects undergoing T-tube drainage of bile, radioactive bile salts introduced into the colon were recovered from the bile mainly within the first 24 hr. Unconjugated cholate and deoxycholate were absorbed more efficiently than a conjugated bile salt taurocholate. Cholate and taurocholate were recovered largely in dehydroxylated form as conjugates of deoxycholate. These findings confirm that the human colon plays 2 roles in bile salt metabolism: bacterial dehydroxylation and absorption.

2865 BIOCHEMICAL AND PHARMACOLOGICAL EFFECTS OF LOCALIZED IRRADIATION OF THE INTESTINE. *(Fr.)*

Santini, R.; Brard, E.; Killian, J. (I.N.S.A., Villeurbanne, France). *C. R. Soc. Biol.* 167(8/9): 1129-1135, 1973.

The effect of local irradiation (800 r) of the intestine was studied on the monoamine oxidase activity in the terminal ileum of the guinea pig and on the contents of acetylcholine and cholinesterase in the duodenum and serotonin in the ileum of the rat. In the irradiated intestine and segments above and below it, acetylcholine contents decreased within the first 24 hr after irradiation and then increased to levels significantly higher than the original ones on the second day. This was followed by a more pronounced drop than the first one on day 4. On day 14 the acetylcholine content was 100% above the original value above the irradiated intestine and was 30% higher below the irradiated segment. Values gradually returned to normal in the irradiated segment. Total cholinesterase activity decreased 20-35% immediately after irradiation. On day 2 values normalized above the irradiated intestine and increased 40% in that below the irradiated segment. These values normalized throughout the intestine after 1 week. Serotonin contents decreased 80% in irradiated intestine and 50% above the irradiated portion after 24 hr. This decrease persisted for 7 days. Serotonin contents essentially normalized above the irradiated intestine within 2 weeks but remained 40% lower than normal in the irradiated portion. Monoamine oxidase activities in the irradiated intestine remained decreased for 1 week and normalized after 14 days; a significant but less persistent decrease occurred below the irradiated portion of the intestine. Pharmacological studies revealed that *in vitro* responses to acetylcholine (2×10^{-3} μg/ml) and serotonin (2×10^{-2} μg/ml) decreased after irradiation; this decreased response was of shorter duration for serotonin. This was followed by an increased response in nonirradiated portions of the intestine, particularly with acetylcholine.

2866 EFFECTS OF DIETARY CALCIUM RESTRICTION AND CHRONIC THYROPARATHYROIDECTOMY ON THE METABOLISM OF (^{3}H)25-HYDROXYVITAMIN D_3 AND THE ACTIVE TRANSPORT OF CALCIUM BY RAT INTESTINE. *(E.)*

Favus, M. J.; Walling, M. W.; Kimberg, D. V. (Harvard Med. Sch., Boston, Mass.). *J. Clin. Invest.* 53(4):1139-1148, 1974.

The chronic effects of both dietary calcium restriction and the absence of parathyroid hormone on the metabolism of 1,25-dihydroxyvitamin D_3 and duodenal calcium-active transport were studied in male albino Sherman rats given thyroid replacement. These relatively long-term studies confirm earlier observations which indicated that the adaptation of calcium absorption to a low calcium intake occurs in both sham-operated and thyroparathyroidectomized animals. The studies also demonstrate that despite reduced levels of 1,25-dihydroxyvitamin D_3 in the plasma of chronically thyroparathyroidectomized animals fed a low calcium diet, the accumulation of this metabolite in at least one target tissue, intestinal mucosa, is identical in both the sham-operated and thyroparathyroidectomized groups. A reduced, but continued level of 1,25-dihydroxyvitamin D_3 production, together with its selective accumulation by intestinal mucosa, probably explains the calcium adaptation which is observed in spite of the chronic absence of the parathyroid glands.

2867 THE MECHANISM OF BICARBONATE SECRETION IN RABBIT ILEUM EXPOSED TO CHOLERAGEN. *(E.)*

Hubel, K. A. (Dept. Med., Univ. Iowa, Iowa City). *J. Clin. Invest.* 53(4):964-970, 1974.

Net movement of H_2O and HCO_3-, and changes in pH and pCO_2 in lumenal fluid were studied in adjacent segments of rabbit ileum *in vivo*, one of which was exposed to choleragen (2.0 mg in 4 ml saline). Four hr after exposure, segments were drained and infused with gassed Krebs-Henseleit solution whose pCO_2 exceeded arterial pCO_2. After 45 min, fluid was collected anaerobically from control and cholera segments. Among 13 cholera segments, lumenal pCO_2 diminished by a mean of 8.4 torr and was less than femoral arterial blood in 6 instances. In the paired control segments, mean pCO_2 increased by 4.4 torr, and was always greater than arterial pCO_2. Dilution could not account for the low pCO_2 in cholera segments because in hypertonic solutions that caused water to move into the lumen, the pCO_2 did not differ from control values obtained with isotonic solutions. The results suggest that OH^- accumulation causes HCO_3^- secretion in cholera.

2868 REVERSAL OF CYCLIC AMP-MEDIATED INTESTINAL SECRETION BY ETHACRYNIC ACID. *(E.)* Al-Awqati, A.; Field, M.; Greenough, III, W. B. (Johns Hopkins Hosp., Baltimore, Md.). *J. Clin. Invest.* 53(3):687-692, 1974.

Unidirectional, transmural fluxes of ^{22}Na and ^{36}Cl were measured across isolated rabbit ileal mucosa. Under control conditions (short-circuited mucosa bathed in bicarbonate-Ringer), there was net absorption of Na and Cl. Theophylline (10 mM), cyclic AMP (5 mM), and cholera toxin (added *in vivo*) abolished net Na flux and produced net Cl secretion. In the presence of theophylline or cAMP, addition of 0.1 mM ethacrynic acid to the serosal bathing solution abolished net Cl secretion and restored net Na absorption. Cholera toxin-treated mucosa was exposed to 0.05 and 1.0 mM ethacrynic acid. The lower concentration restored net Na absorption but did not significantly reduce Cl secretion. The higher concentration abolished net transport of both Na and Cl. Short-circuit current and Na flux measurements in the presence and absence of glucose indicated that 0.1 mM ethacrynic acid suggested that even this concentration of ethacrynic acid does not inhibit glucose-coupled Na transport. Thus ethacrynic acid appears to specifically inhibit Cl (or NaCl) secretion without inhibiting the absorptive Na "pump". The antisecretory effect of 0.1 mM ethacrynic acid does not appear to result from inhibition of adenylate cyclase since secretion stimulated by addition of 5 mM cyclic AMP was abolished. Furthermore, 0.1 mM ethacrynic acid did not significantly reduce theophylline-augmented and cholera toxin-augmented cyclic AMP levels in ileal mucosa. It is concluded that ethacrynic acid interacts specifically with the active Cl (or NaCl) secretory mechanism of the small intestine at a step beyond generation of cyclic AMP.

2869 EFFECTS OF PROSTAGLANDINS AND CHOLERA ENTEROTOXIN ON INTESTINAL MUCOSAL CYCLIC AMP ACCUMULATION: EVIDENCE AGAINST AN ESSENTIAL ROLE FOR PROSTAGLANDINS IN THE ACTION OF TOXIN. *(E.)* Kimberg, D. V.; Field, M.; Gershon, E.; Henderson, A. (Harvard Med. Sch., Boston, Mass.). *J. Clin. Invest.* 53(3):941-949, 1974.

The effects of prostaglandins and cholera enterotoxin on cyclic AMP accumulation in rabbit ileal mucosa were examined *in vitro*. Addition of 5 μg/ml (75 μg/150 mg mucosa) of purified cholera enterotoxin produced a peak increase in cyclic AMP level in 3 hr but there was a time delay of at least 30 min before any effect was observed. Inhibition of cyclic nucleotide phosphodiesterase with theophylline (5 mM) failed to reduce this time delay. In contrast, addition of prostaglandin E_1 (PGE_1) increased the cyclic AMP level rapidly, a peak effect being observed in 2 min. The time of the peak prostaglandin-induced changes in cyclic AMP level and short-circuit current correlated closely. A maximal increment in cyclic AMP level was achieved with 5×10^{-5} M PGE_1. When 10^{-4} M PGE_1 was added to mucosa already maximally stimulated with cholera toxin, the resulting cyclic AMP level was equal to the sum of the levels reached when each agent was added alone. The effects of the enterotoxin on mucosal cyclic AMP levels were not influenced by indomethacin (5.0×10^{-5} M) under conditions where mucosal prostaglandins synthesis was inhibited. The results suggest that endogenous prostaglandins do not provide an essential link in the activation of intestinal mucosal adenyl cyclase by cholera enterotoxin. The effect of cholera enterotoxin on intestinal mucosal cyclic AMP metabolism involves a definite time delay which is not due to cyclic nucleotide phosphodiesterase activity.

GENERAL

2879 EFFECTS OF THE C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ ON SPLANCHNIC CIRCULATION IN THE DOG. *(E.)* Thulin, L. (Karolinska Inst., Stockholm, Sweden). *Acta Chir. Scand.* 139(8): 687-690, 1973.

The vascular effects of the C-terminal octapeptide of cholecystokinin (CCK) were studied in 3 anaesthetized dogs. By using an electromagnetic flowmeter, blood flow was measured in the hepatic artery proper, the superior mesenteric artery and the portal vein. The superior pancreatico-duodenal artery was ligated and cholecystectomy was performed. Systemic, caval and portal pressures were recorded. A total of 40 infusions of 1/2-2 min duration were administered, 21 into the caval and 19 into the portal vein, in doses ranging from 0.5 to 6.5 Ivy dog units/kg/min. After CCK-octapeptide, the systemic blood pressure fell with an average of 5 mmHg. The blood flow increased by 24-36% of pre-infusion values, with no significant difference between infusion sites or dosages. The responses appeared immediately in the hepatic artery and after 1 min delay in the mesenteric artery and the portal vein. The vascular resistance decreased with 19-26%, with no significant difference between infusion sites or dosages. The blood pressure fall was probably due to vasodilation of splanchnic vessels. The delayed response in the mesenteric artery and the portal vein suggests that recirculation is of importance for the effect in these vessels, compared with the more immediate response in the hepatic artery proper. The natural CCK had a weaker effect when infused into the portal than into the caval vein, indicating a certain hepatic inactivation. The octapeptide had almost equal effects after caval and portal infusion, indicating that such a mechanism is of less importance.

2880 IMMUNOGLOBULINS AND OTHER SERUM PROTEINS IN FECES FROM INFANTS AND CHILDREN. *(E.)* Haneberg, B.; Tonder, O. (Sch. Med., Univ. Bergen, Norway). *Scand. J. Immunol.* 2(4):375-383, 1973.

Feces were collected for 9 infants (1-5 months old) and 5 children (2-12 yr old), none of whom showed signs of infections or gastrointestinal dysfunction. Unconcentrated extracts of the freeze-dried feces were screened for immunoglobulins using double diffusion techniques. IgA was present in all 14 extracts, IgG in 6, and IgM in 8. The α-chain determinants in the fecal secretions was identical to those in serum and saliva. The lowest detectable concentrations were 0.5 mg/100 ml for IgA, 0.7 mg/100 ml for IgG, and 0.8 mg/100 ml for IgM. All individua tested have serum IgA, IgG, and IgM levels within normal limits. There were no age variations in the secretion of the intestinal immunoglobulins. Most of the immunoglobulins were easily dissolved in saline. With regard to other serum proteins, α_1 antitrypsin was present in all the fecal samples while α_1 antichymotrypsin was found in 9 and α_1 macroglobulin in 5. Albumin in trace amounts was found in 3 of the samples.

2881 INTERACTION BETWEEN ESCHERICHIA COLI AND SHIGELLA FLEXNERI IN THE DIGESTIVE TRACT OF "GNOTOBIOTIC" MICE. *(E.)* Ducluzeau, R.; Raibaud, P. (Lab. Microb. Ecol., C.N.R.Z., Jouy-en-Josas, France). *Infect. Immun.* 9(4):730-733, 1974.

A strain of *Shigella flexneri* was implanted in the digestive tract of germfree C_3H mice, which were exposed 1 day later to a strain of *Escherichia coli*. The *S. flexneri* were eliminated within 8 days. However, when *S. flexneri* were monoassociated with germfree mice in the absence of *E. coli*, a population of *S. flexneri* appeared which was resistant to the antagonistic effects of *E. coli in vivo*. The emergence of this population appeared to occur *via* a stepwise process which extended over a period of 3 months. The interaction between *S. flexneri* and *E. coli in vivo* and *in vitro* was significantly different in that the *Shigella* capable of coexisting with *E. coli* in the digestive tract were suppressed by the organism *in vitro*. Selection by the host of such mutants as the resistant *S. flexneri* in a bacterial population could constitute one step in the establishment of an autochthonous microflora in the digestive tract.

2882 PORTACAVAL TRANSPOSITION IN THE RAT: A NEW TECHNIQUE AND ITS EFFECTS ON LIVER AND BODY WEIGHT. *(E.)* Ryan, C. J.; Benjamin, I. S.; Blumgart, L. H. (Roy. Infirm., Glasgow, Scotland). *Br. J. Surg.* 61(3):224-228, 1974.

Portacaval transposition by direct end-to-end anastomoses was established in male Sprague-Dawley rats

ith negligible mortality and with survival of up
› 150 days. The operation was associated with an
arly fall in body weight, followed by a recovery
eriod, the rapidity of which was related to the
reoperative weight and age of the animal. At
acrifice 35 days after surgery, the relative liver
eight of the animals with portacaval transposition
as significantly reduced although it remained sig-
ificantly higher than that in a group of animals
ith a portacaval shunt. The only histological
lange was minimal congestion of the sinusoids in
ne animals with portacaval transposition.

83 RADIOIMMUNOASSAY FOR GASTRIC INHIBITORY
POLYPEPTIDE. *(E.)* Kuzio, M.; Dryburgh,
R.; Malloy, K. M.; Brown, J. C. (Dept. Physiol.,
iv. British Columbia, Vancouver, Canada). *Gastro-
terology* 66(3):357-364, 1974.

specific radioimmunoassay for gastric inhibitory
lypeptide has been developed using guinea pig
tisera raised to porcine gastric inhibitory poly-
ptide. Highly purified ^{125}I-porcine gastric in-
bitory polypeptide, further purified on Sephadex
15 after labeling, was employed as a tracer. The
nsitivity range is 25 to 250 pg. No cross reacti-
ty could be demonstrated with gastrin, glucagon,
cretin, cholecystokinin-pancreozymin, motilin, or
soactive intestinal peptide. Reproducibility of
terminations in different assays was demonstrated.
e mean fasting serum concentration was 237 pg/ml
48 normal humans. The serum concentrations in-
eased to above 1200 pg after a meal.

84 SPECIFIC BINDING OF CHOLERA TOXIN TO ISO-
LATED INTESTINAL MICROVILLOUS MEMBRANES.
.) Walker, W. A.; Field, M.; Isselbacher, K. J.
arvard Med. Sch., Boston, Mass.). *Proc. Natl.
ad. Sci. USA* 71(2):320-324, 1974.

sucrose density gradient assay was used to demon-
rate the specificity and saturation of the binding
(^{125}I)cholera toxin to isolated intestinal
crovillous membranes from Sprague-Dawley rat in-
stine. Cholera toxin bound to the microvillous
mbranes at concentrations which produce the usual
ologic response of increased intestinal secretion.
e binding capacity appears to be saturable, which
ggests that a finite number of toxin binding sites
ist per μg of microvillous membrane. When two
ner proteins (bovine serum albumin and IgG) were
xed with intestinal membranes and placed on a
crose gradient, no binding could be demonstrated.
e affinity of cholera toxin for small intestine
thus much stronger than that of other proteins
own to adsorb to epithelial cell surfaces. When
olera toxin was complexed with antitoxin, the
nding of the toxin was inhibited. Toxin attach-
nt to intestinal binding sites was also inhibited
choleragenoid. Similar concentrations of labeled
xin stimulated the accumulation of cyclic AMP in
cosal homogenates and increased the secretion of
uid into intestinal loops, whereas the same
ncentrations of toxin mixed with antitoxin had
effect on cyclic AMP accumulation. These stud-
s suggest that cholera toxin attaches to brush border binding sites before exerting its biologic effect and that local intestinal antibody protection against cholera toxin may be due to inhibition of toxin attachment to these binding sites.

2885 DISSIMILATION OF TRYPTOPHAN AND RELATED INDOLIC COMPOUNDS BY RUMINAL MICROORGANISMS IN VITRO. *(E.)* Yokoyama, M. T.; Carlson, J. R. (Dept. Anim. Sci., Washington State Univ., Pullman). *Appl. Microbiol.* 27(3):540-548, 1974.

Intraruminal doses of L-tryptophan cause acute pulmonary edema and emphysema in cattle. The D and L isomers of tryptophan and 22 related indolic compounds were incubated with ruminal microorganisms *in vitro*. The incubation of L-(U-benzene ring-^{14}C)-tryptophan with ruminal microorganisms for 24 hr resulted in 39% of the added radioactivity being incorporated into skatole, 7% into indole, and 4% into indoleacetate (IAA). D-Tryptophan was not degraded to any of these metabolites. The major pathway of skatole formation from L-tryptophan appeared to be *via* the decarboxylation of IAA. The incubation of (2-^{14}C)IAA with ruminal microorganisms for 24 hr resulted in 38% incorporation into skatole. L-(5-Hydroxy)tryptophan was degraded into 5-hydroxyskatole and 5-hydroxyindole, whereas 5-hydroxyindoleacetate was degraded only to 5-hydroxyskatole. The incubation of indolepyruvate, indolelactate, and indolealdehyde with ruminal microorganisms resulted in the formation of both skatole and indole. Under similar conditions, indoleacetaldehyde was converted to IAA and tryptophol. The addition of increasing concentrations of glucose (0 to 110 mM) reduced the formation of both skatole and indole from L-tryptophan and resulted in the accumulation of IAA. Antibiotics reduced the degradation of L-tryptophan to skatole and indole, with kanamycin and neomycin being particularly effective in reducing the decarboxylation of IAA to skatole.

DIAGNOSTIC PROCEDURES

2915 ISCHEMIC COLITIS DIAGNOSED BY EARLY COLONOSCOPY. *(E.)* McNeill, C.; Green, G.; Bannayan, G.; Weser, E. (Univ. Texas Med. Sch., San Antonio). *Gastrointest. Endosc.* 20(3):124-126, 1974.

A patient is described in whom colonoscopy with biopsy established ischemic injury as the etiology for painless rectal hemorrhage. A 59-yr-old Mexican-American laborer was admitted to the hospital because of a painful mass in his left inguinal region. The pain increased in intensity over 2 days, and he developed progressive nausea and vomiting. The patient denied previous abdominal pain, diarrhea, rectal bleeding, black stools, or other gastrointestinal symptoms. An emergency left inguinal herniorrhaphy was performed. At operation, an incarcerated, but not ischemic appearing colon was found in the hernia sac. Four hours postoperatively, the patient developed dark, painless, bloody diarrhea. Proctoscopy showed a normal mucosa with blood coming from above 20 cm. Ten hours postoperatively colonoscopy was performed. A 30 cm segment of descending colon just distal to the splenic flexure was observed to have a hemorrhagic, friable, and ulcerative mucosa. Biopsy of the involved region showed loss of mucosal epithelium, submucosa, edema, and hemorrhage, and ghost-like bare crypts, typical of an ischemic insult. Reoperation was avoided and the patient made a rapid, uneventful recovery.

2916 HEPATITIS AND BILIARY ATRESIA: MEASURING SERUM-ALPHA-FETOPROTEIN. *(E.)* Zeltzer, P. M.; Neerhout, R. C.; Fonkalsrud, E. W.; Stiehm, E. R. (Univ. California, Sch. Med., Los Angeles). *Lancet* 1(7854):373-375, 1974.

Using a qualitative Ouchterlony double-diffusion procedure with specific antiserum, α-fetoprotein was detected in the serum of 10 of 11 infants with neonatal hepatitis, and was absent in the serum of 7 of 8 infants with biliary atresia. These differences were confirmed by a quantitative radial diffusion immunoassay, in which the peak levels of serum α-fetoprotein in neonatal hepatitis were significantly higher than in biliary atresia. An α-fetoprotein concentration of 4.0 mg/100 ml or greater was regularly associated with neonatal hepatitis. α-Fetoprotein concentrations remained high throughout the course of the hepatitis, reaching peak levels slightly later than serum-bilirubin or serum-transaminase. It is postulated that the compensatory response to neonatal hepatitis by the liver parenchyma is proliferation, retrodifferentiation, and renewal of α-fetoprotein synthesis. By contrast, the compensatory response to biliary atresia is proliferation of biliary tissue incapable of α-fetoprotein synthesis.

2917 ENDOSCOPIC DIAGNOSIS OF ESOPHAGEAL INFLAMMATION. *(E.)* Hattori, K.; Winans, C. S.; Archer, F.; Kirsner, J. B. (Dept. Med., Univ. Chicago, Ill.). *Gastrointest. Endosc.* 20(3): 102-104, 1974.

The histologic appearance of biopsy specimens from the distal esophagus of 10 normal subjects and 57 patients with endoscopic evidence of esophagitis has been reviewed. While only 10% of normal subjects demonstrated a polymorphonuclear leukocyte infiltrate of the mucosa or lamina propria, such an infiltrate was present in 81.1% of esophagitis patients with erythema (11), 83.8% of those with erosions (31), and 80% of those with nodularity (15). Mononuclear cell infiltrates of the lamina propria were seen in both normal and esophagitis patients and their presence does not seem to be a useful criterion for the diagnosis of esophagitis. Careful inspection of the vascular pattern of the distal esophagus with fiberoptic endoscope is helpful in detecting cases of mild esophagitis, and a fine nodularity of the mucosa on close inspection is also a useful sign of esophageal inflammation.

2918 TECHNETIUM-99m PERTECHNETATE IMAGING IN DIAGNOSIS OF MECKEL'S DIVERTICULUM. *(E.)* Leonidas, J. C.; German, D. R. (Children's Mercy St. Luke's Hosp., Kansas City, Mo.). *Arch. Dis. Child.* 49(1):21-26, 1974.

Technetium-99m pertechnetate imaging was performed on 13 patients (6 males and 7 females, aged 1 day to 16 yr) suspected of having Meckel's diverticulum, mainly because of unexplained rectal bleeding (11 cases). The patients were injected i.v. with 100 μCi of ^{99m}Tc pertechnetate, and images of the abdomen were made at 15, 30, and 45 min after injection. Radionuclide imaging was positive in 3 cases. In 2 of these cases subsequent laparotomy confirmed the presence of a Meckel's diverticulum with ectopic gastric mucosa. In both cases conventional x-ray studies had been repeatedly negative. The 3rd patient with a positive scan refused surgery, but the gastric mucosa in an ectopic location in this case represented either a Meckel's diverticulum or a duplication with ectopic gastric mucosa. A Meckel's diverticulum was also found in 1 of 2 cases who had laparotomies despite negative scans; contrast x-ray studies were negative in this patient. It is concluded that abdominal imaging is useful in the preoperative diagnosis of symptomatic Meckel's diverticulum.

2919 γ-GLUTAMYL TRANSPEPTIDASE AND 5'-NUCLEOTIDASE: COMPARISON AS DIAGNOSTICS FOR HEPATIC DISEASE. *(E.)* Boone, D. J.; Routh, J. I.; Schrantz, R. (Dept. Path., Univ. Iowa, Iowa City). *Am. J. Clin. Pathol.* 61(3):321-327, 1974.

The enzymic activities of γ-glutamyl transpeptidase and 5'-nucleotidase were evaluated in 189 patients in whom hepatobiliary-tree disease was suspected. γ-Glutamyl transpeptidase was a better indicator of diseases of the liver, bile duct, and pancreas than was 5'-nucleotidase in 9 out of 10 conditions studied. 5'-Nucleotidase was almost as useful as γ-glutamyl transpeptidase in indicating hepatobiliary disease in patients with granuloma of the liver, acute pancreatitis, congestive heart failure, rheumatoid arthritis, and carcinoma metastatic to the liver. γ-Glutamyl transpeptidase was most elevated in patients with primary carcinoma of the pancreas. Patients with carcinoma metastatic to bone or with neurologic conditions had both enzymes elevated, but elevations occurred in a much lower proportion of these patients than patients with hepatobiliary-tree disease. Liver scan findings correlated better with γ-glutamyl transpeptidase than with 5'-nucleotidase or alkaline phosphatase enzymic activity.

2920 AMOEBIC ABSCESS OF THE LIVER: SCANNING AND SELECTIVE HEPATIC ARTERIOGRAPHY. *(E.)*

Viana, R. L.; Rego, A.; Dias, F. A. A. (Dept. Med. III, Univ. Lourenco Marques, Mozambique). *S. Afr. Med. J.* 48(3):96-100, 1974.

Twenty patients with amoebic abscess of the liver were submitted to clinical, radiological, parasitological, hematological, and isotopic scanning with rose bengal, selective arteriographic examinations, and liver function tests. In the 16 patients submitted to isotopic scanning, the procedure showed morphological and topographical changes with enlargement of the liver in all cases. A lesion was evident in 11 cases, absent in 2, and doubtful in 3. Isotopic scanning failed to show lesions in 2 confirmed cases of amebic abscess of the liver, but it did show a lesion in 1 case of amebic hepatitis. Selective hepatic arteriography indicated liver abscess in 15 cases, extrahepatic abscess in 1 case, no lesion in 1 case, and doubtful lesions in 2 cases. Selective hepatic arteriography was informative concerning the site of lesions in abscess cases, but did not show any change in a case of amebic hepatitis. Both isotopic scanning and selective arteriography failed to demonstrate a small abscess in the tip of the left lobe of the liver. Both methods gave evidence of cure and disappearance of the abscess in the majority of patients given medical treatment. In 1 case, the isotopic scanning showed an existing lesion after treatment which was not confirmed by arteriography. The accuracy of the 2 methods in detecting amebic abscesses of the liver is comparable, but arteriography offers additional advantages in that it enables diagnosis of the nature of the lesions and allows the progress of the condition to be followed.

2921 LIVER SCAN IN HYPERLIPOPROTEINEMIA. *(E.)*

Sachs, B. A.; Bardfeld, P. A.; Bodian, J. E.; Sugarman, L. A.; Hellman, L. (Albert Einstein Coll. Med., Bronx, N. Y.). *JAMA* 227(8):907-910, 1974.

Liver scans with technetium 99m sulfur colloid were obtained in 48 subjects (24 women and 24 men, aged 37-76 yr) with hyperlipoproteinemia who were being treated with various lipid-lowering drug regimens or were receiving no therapy. Liver scans were abnormal in 27 of the 48 cases, but the abnormalities could not be firmly attributed to a specific lipoprotein phenotype or treatment regimen. Of the 27 abnormal liver scans, 21 showed a patchy decrease in uptake; 3, both patchy and focal decreases in uptake; and 3, only focal decreases in uptake. Of the 21 patients with elevated triglyceride levels, 15 (71%) had abnormal liver scans. Hypertriglyceridemia was present in 55% of the subjects with abnormal liver scans compared to 28% of the subjects in whom the scans were normal. The average triglyceride level for the subgroup with abnormal liver scans was 324 mg/100 ml compared with 214 mg/100 ml for those with normal scans. Hyperlipoproteinemia should be considered as a possible associated factor in evaluating an abnormal liver scan. The patchy or focal decreases in sulfur colloid uptake may have resulted from a lipoprotein-laden reticuloendothelial system.

2922 SIMULTANEOUS COMBINED PANCREATIC TEST. *(E.)*

Nundy, S.; Shirley, D.; Beales, J. S. M.; O'Higgins, N.; Heaf, R.; Pearse, E. E.; Lavender, J. P.; Baron, J. H. (Roy. Postgrad. Med. Sch., London, England). *Br. Med. J.* 1(5898): 87-90, 1974.

In one morning, with only one intubation of the duodenum, and with no side effects, the following established tests of the pancreas can be performed: exocrine pancreatic secretion of bicarbonate, enzymes, and radioactive selenium, isotopic scanning, hypotonic duodenography, and cytology. Of 48 patients with the possible diagnosis of pancreatic disease, 14 had no pancreatic disease; 5 had stones in the common bile duct; 2 had carcinoma in the hepatic ducts; the other 34 patients had not developed any evidence of pancreatic disease. Three patients with classical attacks of acute pancreatitis were tested. There were 8 patients with chronic pancreatitis and 8 patients with carcinoma. There was no significant difference between the means of the plateau bicarbonate output in each of the 4 groups of patients studied. Cytology correctly forecast 6 of the 7 pancreatic carcinomas and 53 of the 54 noncarcinomas; however, a pancreatic scan was of little help. All but 1 of the patients without pancreatic disease and all those recovering from acute pancreatitis had higher scores than those with chronic pancreatitis. The combined test almost completely discriminated between patients without pancreatic disease, those with chronic pancreatitis, and those with carcinoma of the pancreas.

2923 LIVER BIOPSY AND PROGNOSIS IN ACUTE LIVER FAILURE. *(E.)*

Scotto, J.; Opolon, P.; Eteve, J.; Vergoz, D.; Thomas, M.; Caroli, J. (Hosp. St. Antoine, Paris, France). *Gut* 14(12): 927-933, 1973.

Liver biopsy was performed in 38 patients with fulminant hepatitis and coma and repeated in 22. Stereological estimation of hepatocyte volume was correlated with levels of clotting factors. Early liver biopsy allowed prognosis in 55% of the cases. All patients with a hepatocyte volume of 35% and thromboplastin time less than 11% died; all patients but two with hepatocyte volume greater than 34% and thromboplastin time greater than 10% recovered consciousness (n=9) or at least showed evidence of marked liver regeneration (n=2). On serial liver biopsy a significant increase in hepatocyte volume and clotting factors was only observed in patients who recovered consciousness. The estimated liver cell mass after regeneration in patients who recovered consciousness was greater than 44% and less than 45% in the patients who did not. As no bleeding occurred in any of these 38 patients, serial liver biopsy is suggested as a method for evaluating liver regeneration and prognosis in acute liver failure. Systematically repeated liver biopsy may help to determine the critical cell mass allowing recovery of consciousness and survival after regeneration of the liver. From this preliminary study such a mass would be 45% of the total liver volume.

GASTROINTESTINAL DISEASES

ESOPHAGUS

2973 EFFICACY OF CONTINUOUS INTRA-OESPHAGEAL ANTACID DRIP THERAPY IN THE TREATMENT OF REFLUX OESOPHAGITIS. A QUANTITATIVE ASSESSMENT USING THE ACID PERFUSION TEST. *(E.)* Serebro, H. A.; Friedman, M.; Beck, I. T. (Dept. Med., Univ. Witwatersrand, South Africa). *S. Afr. Med. J.* 47(36): 1656-1659, 1973.

A simple method of determining the efficacy of antacid therapy in the treatment of clinical esophagitis is presented. Antacid pretreatment modifies the patient's response to esophageal acid perfusion, as early as 24 hr after continuous intra-esophageal antacid perfusion is begun, and also by 72 hr after commencement of therapy with oral antacids. This data explains why false negative acid perfusion tests can occur in the presence of biopsy-proved esophagitis, when such patients have been treated with antacids prior to the performance of the acid perfusion tests. Continuous water perfusion therapy is ineffective in modifying the patient's response to acid perfusion of the esophagus. This study demonstrates that the patient's response to acid perfusion of the esophagus may be modified by both oral antacid therapy and continuous antacid therapy. Continuous antacid intra-esophageal drip therapy is superior to oral antacid therapy in the treatment of the esophagitis.

STOMACH

2995 CONTROL OF ACUTE GASTRIC MUCOSAL HEMORRHAGE. INTRA-ARTERIAL INFUSION OF POSTERIOR PITUITARY EXTRACT. *(E.)* Athanasoulis, C. A.; Baum, S.; Waltman, A. C.; Ring, E. J.; Imbembo, A.; Salm, T. J. V. (Massachusetts Gen. Hosp., Boston). *N. Engl. J. Med.* 290(11):597-603, 1974.

During a 23-month period, 50 patients with acute unremitting gastric mucosal hemorrhage underwent angiography. Posterior pituitary extract was selectively infused into the bleeding artery in 37 of these patients, and the hemorrhage was angiographically and clinically controlled in 31 (84%). Four of 6 patients whose bleeding was not controlled required an operation. The remaining 13 of the 50 patients were not infused with posterior pituitary extract, because in 8 of them, it was not technically feasible to catheterize the appropriate artery, and in 5, associated conditions precluded therapy. Ten of these 13 patients required an operation to arrest bleeding. Of the 31 patients whose hemorrhage was controlled with the intra-arterial infusion of posterior pituitary extract, rebleeding occurred in 2 -- in one, 7 days after the infusion and in the other 19 days after initial control and 4 days after a portacaval shunt. In no patient was it necessary to discontinue the infusion because of local or systemic complications.

2996 MALIGNANT GASTRINOMA FOLLOWING TOTAL GASTRECTOMY. *(E.)* Passaro, Jr., E.; Gordon, E. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Arch. Surg.* 108(4):444-448, 1974.

Half of all patients with the Zollinger-Ellison syndrome treated by total gastrectomy will eventually die from their tumor. The clinical course of 4 patients observed for at least 4 yr is discussed. Three patients had liver metastases, responsible for the death of 2 and seriously affecting the third. The fourth had extensive tumor around the pancreas plus mesenteric metastases that were removed. The patient is doing well. Hepatic artery ligation, streptozotocin therapy, and internal radiation of the tumor were tried in an attempt to control the hepatic metastases. Hepatic scans, the serum gastrin response to calcium infusion, and hepatic angiography are useful techniques to assess continued tumor growth following total gastrectomy.

2997 THE INFLUENCE OF BILE ON CANINE GASTRIC SECRETION. *(E.)* Wickbom, G.; Ello, F.; Faith, M.; Woodward, E. R.; Landor, J. H. (Coll. Med., Univ. Florida, Gainesville). *J. Surg. Res.* 16(1):6-12, 1974.

The effect of various types of biliary diversion on the daily secretion of Heidenhain pouches in 18 mongrel dogs was studied. Total external diversion of bile brought about a decrease in gastric secretion while simple internal diversion of bile to the distal gut via Roux-en-Y segment caused significant increase in Heidenhain pouch secretion. The observed increases in secretion could not be accounted for on the basis of impairment of liver function as measured by serial BSP determinations.

Peptic Ulcers

3022 SUPPRESSION OF BETAZOLE-INDUCED DUODENAL ULCERATION IN GUINEA PIGS BY ANTACIDS AND PROPANTHELINE BROMIDE. *(E.)* Ridley, P. T.; Klaiber, M. S.; Eagleton, G. B.; Schlosser, J. H.; Groves, W. G. (Smith Kline, French Labs., Philadelphia, Pa.). *Res. Commun. Chem. Pathol. Pharmacol.* 7(3):583-592, 1974.

A method is described for the production of duodenal ulcers in guinea pigs by the administration of betazole HCl. Only those male albino guinea pigs with a gastric hydrogen ion concentration of more than 130 mEq/L in response to a 50 mg/kg challenge dose of betazole HCl were selected for the ulcer test. Animals in control and treatment groups were injected with 50 mg/kg of betazole HCl, i.m. Food was withheld and water allowed *ad libitum* for 24 hours after which all animals were again administered betazole HCl at the dose level of 50 mg/kg i.m. Propantheline bromide (PB-Br), magnesium-aluminum hydroxide gel (MA), and a concentrated liquid antacid (CLA), were administered at the time of each betazole administration. PB-Br in saline was given s.c. at 16, 8, 4, and 2 mg/kg. Controls received only saline. MA was given orally at the doses of 8, 4, 2, 1, and 0.5 ml/kg. CLA doses were 2, 1, 0.5, and 0.25 ml/kg. A total number of 343 guinea pigs were found with duodenal ulceration. The ulcer incidence ranged from 70 to 100% with a median of 90 and overall mean of 91%. In the placebo group, 55% had superficial erosions, 39% had deep and 6% had perforating ulcers. Both antacid preparations produced dose-related inhibition of duodenal ulceration. PB-Br, at very high doses, produced a dose-related suppression of duodenal lesions. It is concluded that this method offers an approach to study the etiology of mucosal ulceration and to the discovery of novel therapeutic agents that enhance mucosal resistance.

3023 EFFECT OF CALCITONIN ON GASTRIC AND PANCREATIC SECRETION AND PEPTIC ULCER FORMATION IN CATS. *(E.)* Konturek, S. J.; Radecki, T.; Konturek, D.; Dimitrescu, T. (Med. Acad., Krakow, Poland). *Am. J. Dig. Dis.* 19(3):235-241, 1974.

In conscious cats with chronic gastric fistula and the diversion of bile and pancreatic juice to the jejunum, calcitonin (5 U/kg-hr) caused a marked inhibition of near maximal gastric acid response to pentagastrin and to histamine. In cats with chronic pancreatic fistula, calcitonin inhibited near maximal pancreatic response to exogenous secretin, caerulein, and duodenal acidification. Calcitonin prevented the formation of duodenal ulcers in cats infused with pentagastrin and histamine for 36 hours. The antiulcer action of calcitonin can be attributed mainly to its inhibitory action on gastric acid secretion.

3024 LONG-TERM RESULTS OF SURGICAL TREATMENT FOR DUMPING AFTER PARTIAL GASTRECTOMY. *(E.)* Eldh, J.; Kewenter, J.; Kock, N. G.; Olson, P. (Sahlgren's Hosp., Univ. Goteborg, Sweden). *Br. J. Surg.* 61(2):90-93, 1974.

There were 47 patients with moderate or severe dumping after partial gastric resection who were observed for 8 yr. Twenty patients had been treated for dumping by conversion of the gastrojejunostomy to gastroduodenostomy and in 14 patients an isoperistaltic segment of jejunum had been interposed between the gastric remnant and the duodenum. Thirteen patients with postgastrectomy dumping had not been operated upon secondarily and served as controls. About 50% of the patients who were surgically treated for dumping improved during the observation time. In the group of patients treated conservatively for dumping, improvement was recorded in approximately 60%. The finding of frequent socio-psychiatric manifestations in patients with postgastrectomy dumping emphasizes the importance of considering the mental conditions when selecting patients for gastric surgery. The high proportion of patients who improved spontaneously in the control group also stresses the importance of delaying surgical treatment for a time in patients with postgastrectomy dumping.

3025 INHIBITION OF GASTRIN RELEASE AND GASTRIC SECRETION BY CALCITONIN IN PATIENTS WITH PEPTIC ULCER. *(E.)* Becker, H. D.; Reeder, D. D.; Scurry, M. T.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Am. J. Surg.* 127(1):71-75, 1974.

The effect of an i.v. infusion of calcitonin (2 MRCU/kg) on gastric secretion and serum gastrin and serum calcium levels was studied in 8 normal subjects, 6 patients with duodenal ulcer disease, 3 patients with primary hyperparathyroidism, 6 patients with histologically proved Zollinger-Ellison syndrome, and 3 patients with the Zollinger-Ellison syndrome and hyperparathyroidism. Gastric secretion was greatly inhibited in all groups of patients. Serum calcium was significantly diminished only in patients with hypercalcemia. Serum gastrin levels were depressed in all patients with elevated basal gastrin levels. In normal subjects calcitonin strongly inhibited the serum gastrin response to food. These findings suggest that calcitonin may have a regulatory function in the release or catabolism of the hormone gastrin.

3026 EFFECT OF CARBENOXOLONE ON IONIC FLUXES ACROSS NORMAL GASTRIC MUCOSA AND THAT ASSOCIATED WITH GASTRIC ULCER. *(E.)* Ivey, K. J.; Gray, C. (Roy. Prince Alfred Hosp., Camperdown, Australia). *Aust. N.Z. J. Surg.* 3(5):451-456, 1973.

The effect of carbenoxolone on ionic permeability of human gastric mucosa was determined using liquid test meals in 5 healthy subjects. Control solutions contained 160 mM HCl and 25 μc/liter $^{51}CrCl_3$ as nonabsorbable indicator. The test solution contained in addition 100 mg carbenoxolone per 200 ml. No significant differences were found in net H^+, Na^+, K^+, or Cl^- fluxes between control and carbenoxolone studies. In 3 subjects, studies were repeated after 3 weeks of oral therapy with carbenoxolone tablets, 100 mg 3 times a day. This produced no significant alteration of values either in control or carbenoxolone studies. A 24-yr-old patient with a markedly abnormal gastric mucosal barrier was studied during the acute phase of his ulcer and again after radiological healing of the ulcer following 3 months of therapy with carbenoxolone, 100 mg 3 times a day. Ionic permeability of the mucosa remained unaltered despite healing of the ulcer and/or carbenoxolone therapy. When the ulcer recurred, intragastric instillation of the carbenoxolone test solution failed to alter ionic permeability. It is concluded that carbenoxolone does not alter ionic permeability in normal subjects nor does its action in increasing the healing rate of gastric ulcer appear to be due to alteration of ionic permeability.

3027 THE EFFECT OF RED PEPPER (Capsicum frutescens) ON GASTRIC ACID SECRETION. *(E.)* Solanke, T. F. (no affil.). *J. Surg. Res.* 15(6): 385-390, 1973.

The effect of red pepper suspension on gastric acid secretion was studied in 37 patients with proven duodenal ulcer and 44 patients with nonduodenal ulcer disease. Two forms of the red pepper suspension were used: an ordinary red pepper suspension (A), and a suspension with pH adjusted to 7.4 (B). The patients were divided into Groups (A) and (B). Each group had both duodenal and nonduodenal patients. Distilled water was used as a control in each patient. The instillation of the suspension through a nasogastric tube eliminated the burning effect of the red pepper suspension and the admixture of saliva with the test suspension. There was a significant increase in gastric acid secretion after treatment with red pepper in both groups of patients, more especially in duodenal ulcer patients. The results of this study support the idea that the consumption of red pepper leads to increased gastric acid production which may aggravate the symptoms of duodenal ulceration.

3028 INHIBITION OF GASTRIC PLASMIN ACTIVITY BY EPSILON-AMINOCAPROIC ACID. *(E.)* Thomson, J. M.; Turner, L.; Poller, L. (Withington Hosp., South Manchester, England). *Ann. R. Coll. Surg. Engl.* 53(6):340-347, 1973.

Preoperative administration of the antifibrinolytic drug ε-aminocaproic acid prevented the release of plasmin activity following digital compression of the stomach at operation in 13 out of 14 patients with duodenal ulceration. The inhibition of plasmin activity was more effective in patients who received 3 p.o. doses of 0.1 g/kg ε-aminocaproic acid at 6-hr intervals up to 8 hr before operation than in those who received 2 doses, with the final dose given 2-3 hr before operation. In a parallel control series, all of 15 duodenal ulcer patients not given ε-aminocaproic acid showed evidence of plasmin in gastric and peripheral venous blood and of fibrin/fibrinogen breakdown in these same blood samples following similar gastric manipulation. The ε-aminocaproic treated series, apart from 1 patient with pyloric stenosis, showed an increase of plasminogen activator only, presumably due to stress, anesthesia, etc., and no increase of fibrin/fibrinogen breakdown products. Antifibrinolytic drugs may become an important new factor in the management of bleeding from acute gastric erosions.

3029 TRIALS WITH GAVISCON: ITS MODE OF ACTION AND ITS USE IN THE TREATMENT OF DUODENAL ULCERS (A DOUBLE-BLIND TRIAL). *(E.)* Moshal, M. G. (King Edward VIII Hosp., Durban, South Africa). *S. Afr. J. Surg.* 11(3):139-144, 1973.

The *in vivo* and *in vitro* antacid properties and the floating action of Gaviscon were studied. The *in vivo* antacid properties were studied in 6 intubated subjects with the tip of a nasogastric tube in the antrum of the stomach. Two tablets of Gaviscon or placebo were chewed in random fashion in a double-blind trial. An i.m. injection of 6 μg/kg pentagastrin was administered simultaneously. In the first 15 min of collection (begun 20 min after injection), the percent reduction in total acid concentration was 37.3, or lower than for the 2nd sample. On the 2nd day of Gaviscon administration, the percentage reduction in the 1st sample was 43.9. The mean reduction in acid output was 47.8%. The pH of basal and stimulated gastric juice was measured in 6 subjects. Two powdered Gaviscon tablets were added to 10, 20, 30, 40, or 50 ml gastric juice, and the test tube was shaken. In basal gastric juice, the mean initial pH of 1.9 rose to 4.0 when 10 ml of gastric juice was used and to 3.75 with 20 ml. Withdrawal of gastric juice from a patient after ingestion of Gaviscon showed that the Gaviscon floats atop the secretion. The clinical effectiveness of Gaviscon in acute exacerbation of duodenal ulceration was tested in a double-blind random fashion with 54 courses of treatment. Each patient was subjected to duodenoscopy and barium meal before and after a 4-week course of Gaviscon or placebo. The tablets were identical and 2 were chewed with meals and at bedtime. The 22 patients receiving Gaviscon had a satisfactory cure; 13 patients failed to heal. The duodenal ulcers of 6 patients on placebo healed at 4 weeks; 13 failed to heal.

SMALL INTESTINE

3051 CARCINOID TUMORS OF THE GASTROINTESTINAL TRACT. *(E.)* Swensen, S. R.; Snow, E.; Gaisford, W. D. (Latter-day Saints Hosp., Salt Lake City, Utah). *Am. J. Surg.* 126(6):818-822, 1973.

A group of 56 patients (over 2/3rds of whom were females, aged 14-86 yr) underwent treatment for carcinoid tumor of the gastrointestinal tract. Presenting symptoms varied with the location of the tumor. The most common symptom was abdominal pain (25 patients), other symptoms included diarrhea (9), facial flushing (7), nausea and vomiting (3), gastrointestinal bleeding (7), weight loss (5), and abdominal distention (4). The primary location was the ileum (25). Other primary sites included the appendix, rectum, stomach, duodenum, jejunum, and colon. None of the tumors were benign; 80% had distant metastases or local invasion of carcinoid cells, suggesting that carcinoid tumors are aggressive neoplasms with slow but gradual extension into the mucosa and muscularis with eventual lymphatic and hematologic metastasis. Surgical treatment was used in 52 cases. Of the patients with tumor in the ileum, 23 underwent segmental bowel resection and biopsy or resection of metastases. Indications for surgery in the 17 patients with appendiceal carcinoid tumors included signs of localized peritonites and small bowel obstruction. Treatment of metastatic disease consisted of ileo-right colectomy. Simple appendectomy was used for tumors localized in the appendix. Of the 6 with carcinoid tumors of the rectum, 5 underwent excision and 1, abdominoperineal resection. Of the 3 with carcinoid tumors of the colon, treatment consisted of segmental resection, and all died within 15 months. The carcinoid syndrome was evident in 8 patients, for whom treatment consisted of alpha-methyl-dopa, methylsergide, 5-fluorouracil, cyclophosphamide, and analgesic medications. Of the 8, 7 died, but one is alive with the disease 7 yr later. Except in patients with rectal carcinoid or with carcinoid syndrome with elevated urinary levels of 5-hydroxyindole-acetic acid, preoperative diagnosis is rare. The treatment of choice for all carcinoid tumors is surgical appendectomy for appendiceal tumors, right hemicolectomy with patients with large tumors at the appendiceal base or with cecal extension, and excision for tumors smaller than 1.0 cm in the small and large bowel and smaller than 2.0 in the rectum. All 29 patients with localized lesions (excluding 4 postoperative deaths), have thus far survived from 1 to 17 yr.

3052 RADIOISOTOPE DIAGNOSIS OF A MECKEL'S DIVERTICULUM CAUSING INTESTINAL BLEEDING. *(E.)* Keramidas, D. C.; Voyatzis, N. (Aglaias Kyriakou Children's Hosp., Athens, Greece). *Z. Kinderchir.* 13(2):210-212, 1973.

A 5-yr-old boy with a history of bloody stools was subjected to an abdominal scan with ^{99m}Tc-pertechnetate. The stomach shadow and an abnormal uptake in the midabdomen below the gastric shadow were revealed. During subsequent surgery a Meckel's diverticulum was found and resected. An experimental scintogram of the abdomen with the same technique failed to visualize a known Meckel's diverticulum in a 6-yr-old boy without rectal bleeding, although three other cases were preoperatively diagnosed using this method. Thus abdominal scintigram, which is based on the affinity of the radionucleotide for the parietal cells of the gastric mucosa, is valuable but not absolute. Clinical and laboratory studies must be combined with the findings of the scintigram to assure correct diagnosis.

SMALL INTESTINE

Malabsorption

3072 AMINO ACID AND PEPTIDE ABSORPTION IN PATIENTS WITH COELIAC DISEASE AND DERMATITIS HERPETIFORMIS. *(E.)* Silk, D. B. A.; Kumar, P. J.; Perrett, D.; Clark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp., London, England). *Gut* 15(1):1-8, 1974.

A double-lumen perfusion technique was used to study amino acid and peptide absorption in 8 normal subjects, 13 patients with untreated adult celiac disease, and 16 patients with dermatitis herpetiformis who had varying morphological abnormalities of the small bowel. All subjects were perfused with isotonic solutions containing 10 mM glycyl-L-alanine and 10 mM glycine + 10 mM L-alanine. The patients with adult celiac disease had significantly impaired absorption of glycine and L-alanine from the amino acid solution as compared with the control subjects. Amino acid uptake from the dipeptide solution was not significantly impaired, although 4 individual patients showed impaired uptake of both amino acids. In contrast, very few patients with dermatitis herpetiformis showed impaired amino acid absorption from either solution. Sodium absorption from both solutions was impaired when the patients with adult celiac disease and dermatitis herpetiformis with subtotal villous atrophy and partial villous atrophy were studied, and there were patients in each group who secreted sodium and water. The results suggest that the malabsorption of dietary protein is unlikely to occur in dermatitis herpetiformis, but that it may occur and contribute to the protein deficiency seen in some severe cases of adult celiac disease. The impairment of sodium and water absorption provides evidence that there may be functional impairment of the jejunal mucosa in dermatitis herpetiformis as well as in adult celiac disease.

3073 ROLE OF BILE SALTS IN FAT MALABSORPTION OF PREMATURE INFANTS. *(E.)*

Signer, E. Murphy, G. M.; Edkins, S.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, England). *Arch. Dis. Child.* 49(3): 174-180, 1974.

Nine premature infants were fed a diet of human milk, while nine others were fed modified cow's milk. Subsequent to a 72-hr fat balance, a duodenal intubation was performed on the 14th day of life. Total bile acids were determined in serial duodenal aspirates before and after a milk feed. The excretion of bile acid in the feces was measured over a 72 hr period. The infants fed with human milk absorbed fat better (mean fat absorption coefficient 75%) than those receiving the cow's milk formula (mean fat absorption coefficient 60%). In both groups, bile acid concentrations after a meal were often less than that required for the formation of micellar solutions and the solubilization of fat. With human milk, a reasonable fat absorption occurred even with bile acid levels below the critical micellar concentration. In the infants fed the cow's milk formula, impaired fat absorption was correlated with low bile acid levels. The infants fed human milk excreted less bile acids in the stool than did the infants fed the cow's milk formula. In both groups, the fecal loss of bile acids was increased compared with that in older infants and children. The nutrition of newborn premature infants must take into account the bile salt deficiency present in these babies. Human milk or commercially prepared formulas with a fat composition similar to that of human milk should be used. Supplementation of the diet with vitamins A, D, and E is highly desirable.

3074 QUANTITATION OF THE HISTOLOGICAL CHANGES FOUND IN SMALL INTESTINAL BIOPSY SPECIMENS FROM CHILDREN WITH SUSPECTED COELIAC DISEASE. *(E.)*

Risdon, R. A.; Keeling, J. W. (Hosp. Sick Children, London, England). *Gut* 15(1):9-18, 1974.

The histological appearances of 85 peroral small intestinal biopsy specimens from children were quantitatively analyzed to obtained indices of the mucosal volume and the mucosal surface-to-volume ratio. When compared with controls, 'flat' biopsies from children with untreated celiac disease invariably showed much smaller surface-to-volume (c:lh) ratios. The mucosal volumes (h) of these biopsies were, however, significantly increased. Specimens showing less marked abnormalities (partial villous atrophy) had c:lh ratios in an intermediate range, but, like the biopsies from the untreated celiac patients, the h values were significantly increased. In morphologically normal biopsies, the correlation of surface-to-volume ratio with age showed the c:lh ratios were significantly smaller in younger children. Some of these lower c:lh ratios overlapped the range observed in abnormal biopsies showing partial villous atrophy. However, in the atrophic biopsies, additional histological changes, such as abnormalities in the surface epithelial cells and an increased inflammatory cell infiltration of the lamina propria, were invariably present. Slight changes in biopsies from children under 2 yr of age should, therefore, be interpreted cautiously, and should not necessarily be regarded as pathological on the evidence of the villous pattern alone. The quantitative technique employed proved reproducible under normal working conditions, with its greatest practical value lying in the ability to accurately follow serial changes in biopsies from the same patient.

3075 THE RELATIONSHIP BETWEEN STRUCTURE AND FUNCTION OF SMALL INTESTINE IN PATIENTS WITH A SPRUE SYNDROME AND IN HEALTHY CONTROLS. *(E.)*

Bloch, R.; Menge, H.; Lingelbach, B.; Lorenz-Meyer, H.; Haberish, F. J.; Reicken, E. O. (Med. Clin., Philipps Univ., Marburg, Germany). *Klin. Wochenschr.* 51(23):1151-1158, 1973.

The relation between structure and function of the small intestinal mucosa was studied in treated and untreated sprue in 9 patients and in 10 normal individuals. Of the 9 patients, 7 suffered from celiac disease, 1 from intestinal myeloma and 1 from unclassified sprue. Glucose, electrolyte and water absorption, as well as histochemically detectable enzymatic activities served as functional parameters. Villous circumference and height, crypt length and the number of absorptive cells/unit length indicated structural change. Glucose absorption was less than 20% of the control value in patients with untreated sprue and less than 60% in treated sprue. Sodium, potassium and water transport in the untreated condition was reversed, i.e. secreted into the lumen. After treatment, potassium was still secreted, but water and sodium were again absorbed. A highly significant linear relation existed between glucose, sodium, potassium and water absorption on the one hand, and villous height as well as villous circumference and number of absorptive cells/mm length of intestine on the other. The enzymatic activities of the absorptive cells were reduced. However, according to statistical analysis of the structural and functional data, the observed reduction in transport seemed mainly related to decreased surface area.

3076 FAMILIAL STEATORRHOEA WITH CALCIFICATION OF THE BASAL GANGLIA AND MENTAL RETARDATION.

(E.) Cockel, R.; Hill, E. E.; Rushton, D. I.; Smith, B.; Hawkins, C. F. (Queen Elizabeth Hosp., Birmingham, England). *Q. J. Med.* 42(168):771-783, 1973.

Four children, two boys and fraternal twin girls, of a sibship of 16 suffered from malabsorption, mental retardation with calcification of the basal ganglia, and episodes of pseudo-obstruction. The similarity of clinical features and subsequent investigations suggested a congenital disorder and its frequency indicated an autosomal recessive mode of inheritance. Histological studies of the whole alimentary canal removed at necropsy of a 14-yr-old twin who died of bronchopneumonia showed degenerative changes in the argyrophobe cells. Cell nuclei were all shapes and sizes, in many cases impossible to identify as neuronal, and sometimes frankly pyknotic. Argyrophobe cells produce the transmitter substance acetyl choline which initiates contraction of the smooth muscle. Their loss could explain the dilated bowel with attacks of pseudo-obstruction. Similar changes in the brain cells might explain the association between malabsorption and mental retardation.

3077 TRITIATED DIGOXIN XXII: ABSORPTION AND EXCRETION IN MALABSORPTION SYNDROMES.

(E.) Hall, W. H.; Doherty, J. E.; Gammill, J.; Sherwood, J. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Am. J. Med.* 56(4):437-442, 1974.

The effects of a single oral dose of tritium-labeled digoxin were followed in 7-day studies in a control group of 13 subjects without apparent disease and in 12 patients with malabsorption. Conditions existing in these patients included: nontropical sprue (2); gastrectomy (3); steatorrhea (3); diabetes mellitus (1); pancreatic steatorrhea (1); cancer of pancreas (1); regional enteritis (1); pancreatic insufficiency (1); diabetic steatorrhea (1); and rapid transit after vagotomy and pyloroplasty (2). Serum concentrations, serum half life, urine excretion and fecal excretion of digoxin were determined, and selected fecal samples were subjected to thin layer chromatography to estimate major metabolites of digoxin. Results indicated a slight excess of fecal excretion of the drug in malabsorption states, 5.8% of the amount administered. This fecal excess appeared on and was confined to the 1st day after ingestion. The excess fecal excretion was due to shortened transit time in these patients. Serum concentrations were lower in patients with malabsorption only around the time of peak serum concentration from 30 through 90 min after ingestion of the drug. It is noted that the dry sucrose cube form used in 11 of these patients with malabsorption may present digoxin to the gastrointestinal tract in a more soluble form than the tablet and therefore, the conclusion that digoxin is rather well absorbed in patients with malabsorption may apply only when relatively soluble formulations of digoxin are used.

3078 ENTEROTOXIGENIC INTESTINAL BACTERIA IN TROPICAL SPRUE.

(E.) Klipstein, F. A.; Holdeman, L. V.; Corcino, J. J.; Moore, W. E. C. (Trop. Malabsorption Unit, Univ. Rochester, N.Y.). *Ann. Intern. Med.* 79(5):632-651, 1973.

Bacterial growth was seen in cultures of fasting or postprandial midjejunal aspirates from 10 of 11 patients with tropical sprue; 2 of 4 healthy North Americans; and 7 of 9 Puerto Rican control subjects, of whom 2 had diarrhea. Aspirates from the patients with sprue had a significantly higher mean colony count and consisted predominantly of coliform organisms (*Klebsiella penumoniae* in 7, *Enterobacter cloacae* in 2, and *Escherichia coli* in 1). Both symptomatic Puerto Rican control subjects also harbored coliforms. Representative strains of the predominant coliforms isolated from each patient with sprue all produced an enterotoxin that evoked fluid secretion in the rabbit ileal-loop model, and their principal product of fermentation, ethanol, was present in aspirates from 8 of 9 patients tested. In contrast, the jejunal flora of the asymptomatic Puerto Ricans and North Americans consisted either of Gram-positive or obligatedly anaerobic bacteria. None of these subjects had ethanol in their aspirate. These results suggest that tropical sprue is not caused by one infectious agent, but rather is related to persistent enterotoxigenic coliform facteria after an episode of acute gastroenteritis. The abnormal intestinal structure and function of sprue arises from the contined colonization and toxic substance release carried on by these organisms in the small intestine. Resulting malabsorption leads to folate deficiency, resulting in distinct morphological changes. This suggestion is strengthened by the fact that folic acid therapy results in incomplete recovery brought about by partial improvement of the intestinal function whereas antibiotic therapy is associated with prompt intestinal structure and function improvement, leading to eventual reversal of the intestinal abnormalities.

3079 COELIAC DISEASE AND AUTOIMMUNITY.

(E.) Lancaster Smith, M. J.; Swarbrick, E. T.; Perrin, J.; Wright, J. T. (The London Hosp., England). *Postgrad. Med. J.* 50:45-48, 1974.

Among 57 patients with proven adult celiac disease (24 males and 33 females, aged 14-78 yr), 3 also had tyrotoxicosis, 2 insulin dependent diabetes, 3 fibrosing alveolitis, and 1 each had vitiligo, rheumatoid arthritis, and cryptogenic cirrhosis. Autoantibodies were demonstrated in 12 of the 31 patients so tested, 7 of the 12 had one of the above associated conditions. Antireticulin antibodies were found in 7 of 23 patients so tested, and there was a significant association with dietary gluten. These findings support the theory that celiac disease is associated with disturbed immunity and that a predisposition to autoimmunity may exist. It is suggested that, although the majority of patients with celiac disease do not have IgA deficiency, the local and qualitative disturbance which is apparently common in the celiac subject might in the same way predispose to autoimmune processes.

3080 COELIAC DISEASE AND MALIGNANCY. *(E.)* Barry, R. E.; Read, A. E. (Dept. Med., Univ. Bristol, England). *Q. J. Med.* 42(168):665-675, 1973.

Small-bowel epithelial-cell turnover was studied in 18 patients with subtotal atrophy of the jejunal mucosa who presented with malabsorption. Ten of these patients responded well to a gluten-free diet, and 3 of the remaining 8 patients responded to treatment with prednisone. The epithelial cell DNA loss rate was markedly decreased in the unresponsive group when compared with the patients who responded well to the gluten-free diet. In addition, the total mucosal thickness was significantly decreased in the nonresponsive group, while the mean mitotic index for the nonresponsive group was nonsignificantly decreased. Thus, the patients who failed to respond to treatment with a gluten-free diet appeared to have a decreased rate of epithelial cell turnover, i.e., a hypoplastic mucosa. The responsive and nonresponsive groups did not differ in terms of weight loss, fecal-fat excretion, or plasma protein levels. Of the 8 patients who did not respond to a gluten-free diet, 2 were found to have a reticulum-cell sarcoma, 2 a lymphosarcoma of the small bowel, 1 a focal malignancy in mesenteric nodes, and 1 mesenteric lymphadenopathy. One died of primary peritonitis and 1 is apparently well on treatment with oral prednisone 1 yr after presentation.

3081 HYPERTHYROIDISM AND ADULT CELIAC DISEASE. *(E.)* Wall, A. J.; Levinson, J. D.; Refetoff, S. (Dept. Gastroenterol., Univ. Chicago, Ill.). *Am. J. Gastroenterol.* 60(4):387-393, 1973.

A 29-yr-old housewife had nervousness, loss of weight, and diarrhea for 4 yr which responded to prednisone. Elevated serum levels of long-acting thyroid stimulator and thyroxine together with increased uptake of radioiodide by the thyroid gland confirmed the diagnosis of thyrotoxicosis due to Grave's disease. A flat jejunal biopsy, typical of adult celiac disease, was also demonstrated. Diarrhea remitted with gluten withdrawal and mucosal recovery occurred. Relapse was observed when the patient was re-exposed to gluten. Hyperthyroidism responded to treatment with radioiodide. Thyrotoxic patients may have steatorrhea but do not have villous atrophy of the jejunum. In the thyrotoxic laboratory rat, villous hypertrophy has been described. In this case, the absorptive stress of thyrotoxicosis may have unmasked latent celiac disease. This association of 2 disorders with immunologic overtones, one apparently autoimmune, the other a possible sensitivity to a dietary antigen, is of interest. The significane of the association awaits further investigation.

LARGE INTESTINE

3089 CHANGING PATTERNS OF COLORECTAL CARCINOMA. *(E.)* Cady, B.; Persson, A. V.; Monson, D. O.; Maunz, D. L. (Lahey Clin. Fdn., Boston, Mass.). *Cancer* 33(2):422-426, 1974.

Over the 40 years, 1928-1967, 807 surgical specimens of large bowel adenocarcinoma treated by resection were accumulated. These specimens were analyzed for maximum tumor diameter, incidence of lymph node metastases, location within the large bowel, and compared by decade. During this 40-year period, several trends in clinical presentation of disease were noted. Comparing the first to the last decade, the incidence of right colon cancer increased significantly from 7% to 22% of cases, while the relative incidence of sigmoid, rectosigmoid, and rectal carcinomas fell significantly from 80% to 62%. The size of the increasingly frequent right colon cancers was unchanged in recent years, and the incidence of lymph node metastases was constant during the decades studied. In contrast, there was a significant trend toward earlier disease in the sigmoid, rectosigmoid, and rectal cancers, manifested by a statistically significant decrease in the size of the primary cancers, a significant increase to 65% in the frequency of cases without lymph node metastases, and a decrease, to 9%, of cases with metastases to more than 3 lymph nodes. These trends are explained by the early detection techniques of sigmoidoscopy and rectal examination in recent years, by the more aggressive treatment of polyps within the reach of the sigmoidoscope, and by the greater susceptibility of the right colon to cancer in recent decades.

3090 COLONIC RESPONSE TO PENTAZOCINE. *(E.)* Stanciu, C.; Bennett, J. R. (Hull Roy. Infirm., England). *Br. Med. J.* 1(5903):312-313, 1974.

The effects of pentazocine on colonic motor activity were studied in 5 normal subjects, 5 patients with irritable bowel syndrome, and 5 patients with diverticular disease. The drug decreased intraluminal colonic pressures in all patients but 1. Since morphine, which increases intraluminal colonic pressures, is contraindicated in patients with abdominal pain of colonic origin (diverticular disease, irritable bowel syndrome), it is suggested that pentazocine may be a useful drug in such cases.

3091 CARCINOMA OF THE COLON IN PATIENTS UNDER FORTY YEARS OF AGE. *(E.)* Sanfelippo, P. M.; Beahrs, O. H. (Mayo Fdn., Rochester, Minn.). *Surg. Gynecol.* 138(2):169-170, 1974.

During a 12 year period, 118 patients less than 40 years old underwent operation for adenocarcinoma of colorectal origin. The over-all 5 year survival rate was 39%, and the hospital mortality rate was less than 1%. Loss of weight, obstructive symptoms, and a hemoglobin level of less than 12 grams per 100 milliliters at diagnosis all adversely influenced the prognosis. The 5-year survival rate was reduced from 51% for patients with grades 1 and 2 (Broders) lesions to 18% for those with grades 3 and 4 lesions. Patients with Stage C lesions (Dukes) had a 5-year survival rate of 21% compared with 67% for those with lesions of Stages A and B. There was no relationship between the age of the patient and either the grade or the stage of the lesion.

3092 REGIONAL INFUSION CHEMOTHERAPY OF HEPATIC METASTASES FROM CARCINOMA OF THE COLON. *(E.)* Cady, B.; Oberfield, R. A. (Harvard Med. Sch., Boston, Mass.). *Am. J. Surg.* 127(2):220-227, 1974.

The effects of hepatic intra-arterial infusion of 5-fluoro-2'-deoxyuridine (5-FUDR) in 51 consecutive patients with hepatic metastases from carcinoma of the colon were studied. An objective response was recognized in 57% by decreased hepatic size, 61% by improved hepatic scan, 59% by improved biochemical hepatic function tests, and 39% by improved angiograms. These categories of objective response were not always interrelated. Thus, on the basis of at least one objective response and symptomatic improvement, a clinical response rate of 71% was achieved. Patients with a clinical response had a median survival of 16 months; nonresponders had a median survival of 5 months. Factors related to response rate and prolonged survival were young age, absence of ascites, presence of jaundice, and less extensive involvement of the liver. The presence of extrahepatic intra-abdominal metastases did not affect the response rate or survival time, indicating the controlling effect of the hepatic metastases. These response rates are substantially higher than those reported with systemic chemotherapy and indicate that regional chemotherapy of hepatic metastases from carcinoma of the large bowel should be more widely studied and adopted.

3093 AGANGLIONIC MEGACOLON IN PIEBALD-LETHAL MICE. *(E.)* Webster, W. (Dept. Anat., Univ. Virginia, Charlottesville). *Arch Pathol.* 97 (2):111-117, 1974.

The autonomic innervation of the colon was examined histochemically in a strain of mice (piebald-lethal, s^1) that develop congenital aganglionic megacolon. The normal periganglionic adrenergic innervation was completely absent in the aganglionic zone but normally developed in the transitional and ganglionic zones. The cholinergic innervation was more complex. The transitional zone showed a number of ganglia and intermuscular nerves but very few postganglionic intramuscular motor nerves. The proximal aganglionic zone was almost denervated; there was a number of intermuscular nerves but few in the muscle layers. The distal aganglionic zone varied in appearance and length; it was usually characterized by an almost normal number of intramuscular nerve fibers Obstruction was considered to be primarily due to the denervated proximal aganglionic zone; this obstruction was enhanced by the presumably poor propulsive power of the transitional zone.

Ulcerative Colitis

08 THE PROGNOSIS OF ULCERATIVE COLITIS. *(E.)* Bonnevie, O.; Binder, V.; Anthonisen, P.; is, P. (Gentofte Univ. Hosp., Hellerup, Denmark). *and. J. Gastroenterol.* 9(1):81-91, 1974.

regional and representative group of 332 patients s studied to determine the prognosis of ulceraive colitis. The results of the investigation into e prognosis of ulcerative colitis seem to indicate at 1) male patients, 2) patients diagnosed at a te age, and 3) patients diagnosed shortly after e clinical debut show the greater probability of ing from ulcerative colitis. In patients tolerat-g salazosulphapyridine, this drug constituted the basic medical treatment, in doses of 3 to 4 g daily in acute cases, and of 1 to 2 g as long-term treatment. When this treatment proved insufficient local and universal corticosteroids were given. If the clinical condition did not improve or if the condition worsened, surgery was undertaken. Indications for surgery were 1) acute, severe cases, 2) chronic courses, 3) signs of permanent strictures, 4) retarded growth, and 5) cases of symptoms for more than 10 years. The operations were: 1) primary total proctocolectomy with ileostomy, 2) total colectomy with ileostomy and retained rectal stump, 3) total colectomy with primary ileorectal anastomosis, 4) secondary rectal extirpation after total colectomy with ileostomy, and 5) secondary ileorectal anastomosis following a primary total colectomy with ileostomy. No excess of deaths occurred as a result of ulcerative colitis in patients treated exclusive on medical lines. The early postoperative fatality was the same whether surgery was undertaken at the time of the first attack, or after 1, 2, or 3 years of treatment and observation.

PANCREAS

Pancreatitis

3115 A CONTROLLED TRIAL OF TRASYLOL IN THE TREATMENT OF ACUTE PANCREATITIS. *(E.)* Trapnell, J. E.; Rigby, C. C.; Talbot, C. H.; Duncan, E. H. L. (Roy. Victoria Hosp., Bournemouth, England). *Br. J. Surg.* 61(3):177-182, 1974.

The effectiveness of Trasylol (800,000 U/day for 5 days i.v.) was tested in a prospective double blind controlled study involving 105 patients in their first proved acute attack of pancreatitis. The patients were managed on an identical strict protocol except that they received either Trasylol A (active Trasylol) or B in a random fashion. At the conclusion of the acute episode, the illness was assessed according to criteria which were not open to observer modification and each attack was categorized as mild, moderate, severe, or fatal. The mortality rate was 7.5% in group A and 25% in group B; the difference is statistically significant. In the Trasylol-treated group the normally observed tendency for mortality to rise with advancing age was abolished. Thus, Trasylol must be regarded as a beneficial drug for the treatment of acute pancreatitis.

3116 ETIOLOGY AND COURSE OF PRIMARY CHRONIC PANCREATITIS IN WESTERN FRANCE. *(E.)* Gastard, J.; Joubaud, F.; Farbos, T.; Loussouarn, J.; Marion, J.; Pannier, M.; Renaudet, F.; Valdazo, R.; Gosselin, M. (Ctr. Hosp., Univ. Rennes, France). *Digestion* 9(5):416-428, 1973.

Primary chronic pancreatitis was studied in 263 male patients from Western France. The incidence of this disease amounted to 0.6% of all patients consulting a gastroenterologist. Considering geological characteristics, chronic pancreatitis was found rarely in patients residing in areas of granitic soils. The age of onset of the disease ranged from 15 to 64 yr, peaking between 30 and 40 yr. Chronic pancreatitis was relatively uncommon in rural areas in contrast to the high incidence of alcoholism in persons living in these areas. For various occupational groups the incidence of this disease vs. the population of the group were: employers, 7.3% (incidence) vs. 9.66% (population); professional classes, 8.5%, 3.8%; middle-management personnel, 8.9%, 6.6%; manual workers, 45.3%, 41.2%; white-collar workers, 6.9%, 6.3%; domestics, 3.2%, 0.9%; and armed forces, 5.7%, 2.8%. Obesity prior to the onset of the disease was a frequent finding, with the excess of calories related to an excessive intake of all nutriments considered. Alcoholism was present in 84.8% of the patients, 36% to a severe degree, consuming more than 200 ml absolute alcohol/day. Pancreatic pain was a feature in 96.6% of these cases id manifested itself in ways varying in frequency id intensity. Complications occurred throughout ie course of the disease, especially during the early ears, and included pancreatic pseudocyst (51 cases), emorrhage from the alimentary tract (13), duodenal tenosis (10), jaundice (25), pericarditis (4), leurisy (16), and psychiatric disorders (12). Studies f the liver revealed that cirrhosis was frequent 28.8%), occurring mainly in agricultural populations, ı older patients, in heavy drinkers, and in patients ıving a disorder in carbohydrate metabolism and ıncreatic calcification. Of the 31 deaths in this eries pancreatitis accounted for 5, and cirrhosis r 10. The high incidence of death from cirrhosis ıdicates the need for withdrawal therapy for alcoılics. Exocrine function was studied in 66 patients ıd was noted that in 40% of these cases, anatomiıl damage was severe enough to cause steatorrhea ı excess of 10 g/day. Surgery was performed in 104 tients including left pancreatectomy (34 cases), ght pancreatectomy (19), total pancreatectomy (2), ıncreaticojejunostomy (28), splanchnicectomy (8), stoanastomosis (4), and shunt operations (9).

17 AN INTERNATIONAL SURVEY ON NUTRITION AND PANCREATITIS. *(E.)* Sarles, H. (Res. Unit. thol. Dis., INSERM, Marseille, France). *Digestion* 5):389-403, 1973.

e frequency of acute and chronic pancreatitis in lation to nutrition has been studied in 16 countries Africa, Latin America, Asia, and Europe. Results this study indicate that nearly 2 people out of ery hundred in the world apparently die from a pan-eatic disease, especially cancer, which alone re-esents 1% of the causes of death in this survey. e incidence of pancreatic cancer appears to be in-easing at a rate of 15% per decade. A great dif-rence in distribution of pancreatic disease ap-ared from one country to another. It was noted at diets rich in proteins and fats are associated th acute pancreatitis and with pancreatic cancer. gh carbohydrate diets (from malnutrition or un-lanced diets) were associated with all pancreatic seases and diets poor in all constituents, except some cases alcohol, were associated with other uses of death. Diets rich in alcohol gave rise chronic calcifying pancreatitis but not acute pan-eatitis or cancer of the pancreas. The age of set of chronic calcifying pancreatitis averaged .4 yr, except for India where it was 12.5 yr, ssibly due to malnutrition in childhood. Onset es for chronic pancreatitis without calcification re similar, but those for acute pancreatitis were gnificantly higher. Patients with chronic calci-ing pancreatitis averaged 10 cm shorter in height an those with acute pancreatitis, suggesting the esence of some defect prior to the onset of this sease, with the clinical manifestations appearing ter the end of the growth period. Weight loss, roblem in this disease, was significantly greater patients with chronic pancreatitis, particularly ose with calcification. It is therefore concluded at acute pancreatitis and chronic calcifying pan-eatitis are quite distinct in both etiology and ographical distribution. There is a significant rrelation between geographical distribution of chronic calcifying pancreatitis and that of pancreatic cancer. Chronic calcifying pancreatitis seems correlated to alcoholism in centers where nutrition is satisfactory and with protein deficiency in others.

3118 CHRONIC CALCIFYING PANCREATITIS AND PANCREATIC CARCINOMA IN JAPAN. *(E.)* Ishii, K.; Nakamura, K.; Takeuchi, T.; Hirayama, T. (Hosp. Natl. Cancer Ctr., Tokyo, Japan). *Digestion* 9(5): 429-437, 1973.

Etiological factors, especially alcohol intake, in the development of chronic calcifying pancreatitis in Japan were studied, including comparisons between some environmental factors with regard to calcifying pancreatitis and pancreatic carcinoma. The study included 150 patients with chronic calcifying pancreatitis (male/female ratio 3.5/1.0, average age 45 yr) and 1,070 patients with carcinoma of the pancreas (male/female ratio 1.9/1.0, 70% were in their 5th and 6th decades of life). Comparisons of occupation, smoking habits, alcohol and food intake were made on male patients over 40 yr of age with calcifying pancreatitis (42 cases) or with carcinoma of the pancreas (311 cases). Frequency of both pancreatic carcinoma and calcifying pancreatitis was significantly higher in professional managing and service workers and significantly lower in agricultural workers when compared to controls. No significant differences between the diseases themselves were observed. In cases of carcinoma of the pancreas, daily intake of meat, fish, milk, and soybean paste soup were significantly higher while daily intake of rice, vegetables, and pickels were significantly lower. No differences in food intake were noted between the calcifying pancreatitis group and controls. In comparing the two diseases, it was noted that the only significant difference was in the daily intake of alcohol which was higher in calcifying pancreatitis patients. As for etiological factors of calcifying pancreatitis, heavy alcohol consumption occurred in 32.6% of the patients, 10.0% had gallstones, 11.3% had previous history of acute pancreatitis, 2.0% had abdominal surgery, 2.6% had hereditary pancreatitis. The relation between the daily intake of alcohol and the exocrine/endocrine functions of the pancreas were described in 145 patients with calcifying pancreatitis. The frequency of exocrine dysfunction of the pancreas was higher in patients drinking large amounts of alcohol.

3119 RECURRENT PANCREATITIS ASSOCIATED WITH NORMOCALCEMIA, PARATHYROID HYPERPLASIA, AND INCREASED SERUM PARATHORMONE. *(E.)* Danzi, J. T.; Farmer, R. G.; Esselstyn, G. B. (Cleveland Clin., Ohio). *Cleve. Clin. Q.* 41(1):39-43, 1974.

A 14 yr old white girl was diagnosed as having severe relapsing pancreatitis associated with a normal serum calcium level, parathyroid hyperplasia, and elevation of serum parathormone level to 3 times the normal range for her age. No pancreatic calcification was present. The nearly normal serum calcium and depressed serum phosphorus levels during an episode of acute pancreatitis were clues to the diagnosis of hyperparathyroidism. In normocalcemic hyperparathyroidism related to pancreatitis, the serum calcium value is normal during the acute episode and the symptom-free intervals. No evidence of pancreatic insufficiency or osteomalacia was found in this patient. In considering the pathogenesis of pancreatitis related to hyperparathyroidism, it was noted that thromboarteritis and focal pancreatic tissue necrosis have resulted in laboratory animals after administration of parathormone, and the direct role of parathormone in the etiology of pancreatitis must therefore be considered. Such an etiology is supported by the elevation of the patient's serum parathormone and the correlation with the patient's symptoms before and after surgery.

3120 NEAR TOTAL PANCREATECTOMY FOR HEMORRHAGIC PANCREATITIS. *(E.)* Norton, L.; Eiseman, B. (Denver Gen. Hosp., Col.). *Am. J. Surg.* 127(2): 191-195, 1974.

Near total pancreatectomy of 65 to 85% was performed in 4 patients (2 males and 2 females, aged 24-47 yr) judged to be dying from acute hemorrhagic pancreatitis. The operation began with mobilization of the spleen to allow left to right dissection of the pancreas. The splenic artery was ligated after division of the spleen's attachments. Retracting the spleen anteriorly allowed identification of the tail of the pancreas, despite surrounding inflammation. A plane of dissection posterior to the pancreas was easily established. Blunt or sharp dissection through inflammatory tissue quickly exposed the pancreas which was peeled from the surrounding edematous hemorrhaging tissue. Dissection proceeded rapidly to the confluence of the splenic and superior mesenteric veins. The splenic vein was then divided. Venous tributaries from the pancreas were usually thrombosed or often divided without trying. Patients with disease of 2 day's duration or less survived despite postoperative complications of respiratory distress syndrome (2), and delirium tremens (1). They were discharged from the hospital 11 to 20 days after surgery. The only late complication was diabetes in 1 case. The 4th patient, who was in a terminal condition when operated on after 1 week of the disease, died 3 weeks after pancreatectomy as a result of sepsis due to intestinal leakage. Recovery was dramatic before the occurrence of sepsis. The primary indication for near total pancreatectomy is failure of nonoperative treatment. The optimal time for surgery appears to be 24 to 48 hr after onset of the disease. Gray-Turner or Cullen's signs were not present in these patients, and diagnostic paracentesis would have failed to confirm the disease in 1 of these cases. None of these patients had abnormally low serum calcium levels prior to surgery. The operation is recommended in patients dying from acute hemorrhagic pancreatitis when nonoperative therapy has failed.

3121 MAJOR GASTROINTESTINAL HEMORRHAGE ASSOCIATED WITH PANCREATIC PSEUDOCYST. *(E.)* Wolstenholme, J. T. (VA Ctr., White River Junction, Vt.). *Am. J. Surg.* 127(4):377-381, 1974.

An aggressive surgical approach was used in 3 male patients (aged 40-50 yr) with pancreatitis complicated by massive bleeding. In 1 case, bleeding originated from a pseudocyst in the head of the pancreas and involved the gastroduodenal artery. This was treated successfully with excision of the cyst and head of the pancreas. Intracystic suture-ligation of the bleeding vessel together with cystogastrostomy was performed in 2 other cases, one a pancreatic pseudocyst with splenic artery hemorrhage and the other a pancreatic pseudocyst with splenic artery erosion. In each case, the aggressive surgery which was undertaken was apparently life-saving. It is felt that in patients with bleeding who are known to have pancreatitis or a pseudocyst, this organ must be considered as a possible site of the hemorrhage. The palpation of an upper abdominal mass may help in establishing the presence of a pseudocyst. If the mass shows a rapid increase or decrease in size, bleeding into or from the cyst should be suspected. The presence of a bruit or pulsations in the upper part of the abdomen would support the vascular nature of the lesion. It is suggested that the celiac axis and superior mesenteric artery angiography be performed prior to barium contrast studies. By demonstrating a pseudocyst-aneurysm, such a study would confirm the diagnosis and, in addition, might identify the leaking vessel, thereby permitting the use of a more precise surgical approach to include isolation and control of the bleeding vessel prior to opening the pseudocyst.

3122 SURGICAL INTERVENTION IN ACUTE NECROTIZING PANCREATITIS. *(E.)* Warshaw, A. L.; Imbembo, A. L.; Civetta, J. M.; Daggett, W. M. (Massachusetts Gen. Hosp., Boston). *Am. J. Surg.* 127(4):484-491, 1974.

Acute pancreatitis in 38 patients was treated with an operation that included cholecystostomy, gastrostomy, feeding jejunostomy, and sump drainage of the peripancreatic lesser sac. Of 11 patients judged to be dying of fulminant pancreatitis in the first 48 hr of treatment, 9 improved immediately and 7 survived. Of 18 who underwent operation because of persistent or increased signs of inflammation 2 weeks after admission, 7 had an immediate favorable response, mainly due to drainage of abscesses, necrotic pancreas, or pseudocysts and 12 survived. Pancreatitis of lesser severity in 9 patients received no apparent benefit from the operation. In 9 patients gastrostomy and jejunostomy were used for prolonged treatment of intestinal dysfunction. In 6 patients the cholecystostomy helped control bacterial cholangitis. In 7 patients the peripancreatic sumps provided tracts for the late drainage of abscesses, pancreatic fistulas, and sloughed pancreas. The major postoperative problem was the development of intra-abdominal abscesses which occurred in 16 patients. Of the 13 deaths in the series, 10 were directly related to these abscesses. The survival of patients with severe pancreatitis resistant to standard medical easures appears to be improved by this operative pproach. It is suggested that an aggressive pproach to re-exploration and drainage of late ancreatic abscesses in patients with necrotizing ancreatitis should improve still further the urvival rate of patients.

123 FAMILIAL HYPERLIPOPROTEINEMIA AND ACUTE PANCREATITIS. STUDY OF ONE FAMILY WITH REDRICKSON'S TYPE I HYPERLIPOPROTEINEMIA. *(Por.)* ott, C. de B.; Brandao, M. I. B.; Ohki, Y. archese, N.; Bettarello, A. (Clin. Hosp., Sao aulo, Brazil). *Arq. Gastroenterol. S. Paulo* 1(1):17-22, 1974.

LIVER AND BILIARY TRACT

130 CHRONIC LIVER DISEASE ASSOCIATED WITH CHILDHOOD ULCERATIVE COLITIS. *(E.)* Tog-ill, P. J.; Benton, K. P. E.; Smith, P. G. (Gen. osp., Nottingham, England). *Postgrad. Med. J.* 0(579):9-15, 1974.

mong 301 patients with ulcerative colitis seen be-ween 1961 and 1971, 48 developed the disease before he age of 20 yr and 4 of the 48 progressed to seri-us liver disease. In the remaining 253 older pa-ients, there were only 3 cases of chronic liver isease. The histories of the 4 childhood cases of olitis and associated liver disease are presented. iver histology in these patients was fibrosis (1), irrhosis (1), sclerosing cholangitis (1), and peri-holangitis (1). The liver lesions of childhood co-itis followed a similar histopathological pattern o those seen in adult colitis, and the hepatic esions in the in patients developing colitis in hildhood were unrelated to the extent, duration, r severity of the colitis. Although the data in-icate that the onset of ulcerative colitis in hildhood carries a considerable risk of subsequent erious liver disease, the precise nature of the elationship remains to be clarified.

131 ARTERIAL INFUSION CHEMOTHERAPY OF HEPATOMA. *(E.)* Cady, B.; Oberfield, R. A. (Lahey lin. Fdn., Boston, Mass.). *Surg. Gynecol. Obstet.* 38(3):381-384, 1974.

f 54 patients with pathologically proven primary arcinoma of the liver, 18 were treated by region rterial infusion chemotherapy, 5 underwent resection, and the remainder, usually untreated, served as nonconcurrent controls. No patient showed any evidence of another primary tumor at any time. Floxuridine (0.3 mg/kg/day) was the primary drug used in all patients, although fluorouracil (3-5 mg/kg/day) was given occasionally and methotrexate (5 mg/kg/day) was used for a period in 1 patient. Five of the 18 patients who were treated with infusion chemotherapy died as a result of the treatment program; all were over 55 yr of age. The median survival time was 16.5 months in the remaining male patients and 8 months in the remaining female patients. Eleven of the 18 patients were definitely symptomatically improved by infusion chemotherapy and 8 patients were substantially improved symptomatically. All instances of significant improvement and only one treatment-related death occurred during the last 5 yr of the study. No patient had a return to normal of all laboratory or clinical features with infusion chemotherapy. A trial of intra-arterial chemotherapy should be undertaken in primary liver cell carcinoma if resection is not possible.

3132 PRIMARY LIVER CANCER: A REVIEW OF THE CLINICAL FEATURES, BLOOD GROUPS, SERUM ENZYMES, THERAPY, AND SURVIVAL OF 65 CASES. *(E.)* Al-Sarraf, M.; Go, T. S.; Kithier, K.; Vaitkevicius, V. K. (Milton Darling Mem. Ctr., Detroit, Mich.). *Cancer* 33(2):574-582, 1974.

Of 65 patients with primary liver cancer, 53 had hepatocarcinomas. Primary cancer of the liver was most frequently observed in patients between 50 and

80 yr of age, and the incidence was three times as great in males as in females. The incidence of hepatocarcinoma was greater among blacks, especially those with blood group B. The most common symptoms associated with primary liver cancer were upper abdominal pain, weakness, and weight loss, while the most commonly observed signs were hepatomegaly or an abdominal mass: jaundice and ascites were also common. Serum alkaline phosphatase, SGOT, SGPT, and LDH were elevated in most of the 65 patients studied. In the patients with hepatocarcinoma, 66% had histologically confirmed liver cirrhosis at autopsy. Serial α-fetoprotein (AFP) tests were performed on 19 patients with hepatoma; AFP was detected in 14 of these. No Australia antigen was detected in 12 patients with hepatoma. Nine of 16 patients had subjective and objective tumor responses with continuous 5-floxuridine hepatic artery infusion. None of the 18 patients treated with systemic cytotoxic agents responded. The difference in response between hepatic artery infusion and systemic therapy is statistically significant. The patients who responded to intrahepatic artery infusion survived significantly longer than the nonresponders and the patients who received systemic chemotherapy. Autopsies were performed on 30 patients with hepatocarcinoma and 9 patients with cholangiocarcinoma. The majority of hepatocarcinoma patients had metastases to the lungs and lymph nodes, while 55% of the cholangiocarcinoma patients had metastases to the bone.

3133 NEEDLE-LIKE CYTOPLASMIC INCLUSIONS IN THE LIVER IN PORPHYRIA CUTANEA TARDA. *(E.)*
Waldo, E. D.; Tobias, H. (VA Hosp., New York, N.Y.). *Arch. Pathol.* 96(6):368-371, 1973.

Liver biopsy specimens from 16 patients with porphyria cutanea tarda (PCT) were examined by light, electron and fluorescence microscopy. Light microscopy revealed the presence of needle-shaped cytoplasmic inclusions in all of the specimens; in most instances these inclusions were present in less than 25% of the cells. When examined with the fluorescence microscope, the inclusions demonstrated the characteristic spectrum of porphyrin fluorescence. The amounts of the fluorescent material seemed to correlate with the presence of lipofuscin deposits within the cells. Other less specific changes associated with hepatic disease were regularly found, but there was no correlation between their severity and the presence or frequency of the needle-shaped inclusions. Electron microscopy showed electrolucent, needle-like areas, usually surrounded by electron-dense areas that appeared lysosomal in character, in 7 of 8 biopsy specimens. The needle-shaped bodies were always found in the cytoplasm of hepatocytes and were generally present singly. In addition, paracrystalline structures consisting of parallel arrays of densely osmophilic bands alternating with light interspaces were present within the mitochondrial matrix in 10-40% of the mitochondria of 3 specimens.

3134 POSTNATAL CYTOMEGALOVIRUS HEPATITIS. AN AUTOPSY AND LIVER BIOPSY STUDY. *(E.)*
Henson, D. E.; Grimley, P. M.; Strano, A. J. (Natl. Cancer Inst., Bethesda, MD). *Hum. Pathol.* 5(1):93-103, 1974.

Cytomegalovirus hepatitis was studied in 13 patients 11 had died during disseminated cytomegalovirus infection and 2 had liver biopsies for suspected hepatitis. Histologically, inclusions were present in liver cells of all 3 lobular zones and less frequently in the vascular endothelium of the portal areas. Infected liver cells were seen in the cords, partially extruded into sinusoids, or within sinusoids where they were surrounded by inflammatory cell that formed small focal lesions. Once surrounded, infected cells degenerated into acidophilic bodies. In portal areas in which inclusions were seen there was a variable infiltration of acute and chronic inflammatory cells. The number of infected cells varied considerably in the livers from different patients. In the 2 patients with liver biopsies, the serum glutamic oxaloacetic transaminase, serum glutamic pyruvic transaminase, and alkaline phosphatase activities were transiently increased. Serological studies in these 2 patients showed high titers of cytomegalovirus hepatitis is characterized by a foca mononuclear cell infiltration in the lobules and a pleomorphic cell infiltration in the portal areas. The lesions associated with virus infected cells are not diagnostic except when intranuclear inclusions are seen. The histological lesions of biopsy proved cytomegalovirus hepatitis resemble the changes seen in livers of patients dying with hepatic involvement during disseminated infection. It is concluded that the diagnosis of cytomegalovirus hepatitis can be made only by finding inclusion bearing cells in the liver. The diagnosis can be inferred by isolating cytomegalovirus or by demonstrating a 4 fold or grea rise in cytomegalovirus antibody titer contemporary with liver function abnormalities or hepatomegaly.

3135 RADIATION THERAPY OF LIVER METASTASES. *(Ger.)* Dalluge, K. H.; Eichhorn, H. J.; Scholz, P.; Huttner, J. (Ctr. Inst. Cancer Res., Robert Rossle Clin., Berlin, Germany). *Strahlentherapie* 144(5):522-532, 1972.

Palliative radiotherapy was administered to 10 patients who had liver metastases as the only metastases from primary carcinomas of the lung (6 cases), esophagus (3 cases), and stomach (1 case). With the exception of the patient with stomach cancer, all patients received radiation over the entire liver with sloping fixed ^{60}Co fields in doses of 50 R HD given at 5-day intervals (total doses of 500-5500 R HD). Responses of these patients were compared with those of 11 patients who received radiotherapy for lung cancer but not for liver metastase since other metastases were present. Liver functio tests and clotting status were investigated at 2-week intervals before, during, and after radiotherap and histological examinations of the liver were performed at autopsy in 9 cases. Radiotherapy caused decreases in serum bilirubin levels in all patients with hyperbilirubinemia. Survival time was only 4- days in the 3 patients with initial increases in SGOT and SGPT activities, while the levels of these enzymes increased in controls about 4 weeks before

eath. It is concluded that radiotherapy shortened
he survival of patients whose transaminase activities
ere initially increased. Survival times in the
emaining 7 patients ranged from 56 to 113 days
average of 2 months). Serum aldolase activities
ere the most reliable criterion for the development
f other metastases. Hyalin formation and the de-
elopment of fibrosis occurred in metastases with
oses of 3900 R HD or more, while severe damage was
oserved in the hepatic parenchyma only when doses
xceeded 5000 R HD. It is concluded that the optimum
ose for palliative irradiation of hepatic metastases
s 4000 R HD.

136 α_1-ANTITRYPSIN DEFICIENCY IN CHRONIC LIVER
DISEASE, AND A REPORT OF CIRRHOSIS AND EM-
HYSEMA IN ADULT MEMBERS OF A FAMILY. *(E.)* Kumar,
.; Lancaster-Smith, M.; Cook, P.; Stansfeld, A.;
lark, M. L.; Dawson, A. M. (St. Bartholomew's Hosp.,
ondon, England). *Br. Med. J.* 1(5904):366-367, 1974.

ie case report of a 25-yr-old man with cirrhosis
nd a childhood history of liver disease is presented
ie patient was subsequently found to have α_1-anti-
ypsin deficiency. The proband's father, aged 56,
id an 8-yr history of emphysema and was also found
have α_1-antitrypsin deficiency. The proband's
other and paternal grandmother showed no evidence
liver or pulmonary disease. Comparatively high
-antitrypsin levels were found in 30 unrelated
ult patients with chronic liver disease. Although
-antitrypsin deficiency is probably a rare cause
symptomatic cirrhosis in adults, it should be
nsidered in adult cirrhotic patients with unusual
thological features when there is no other obvious
iology. Suspicion should also be raised when there
a history of hepatic disease in infancy or child-
od. Homozygous or heterozygous deficiency of α_1-
titrypsin will be common among close relatives of
ch patients.

37 THE CHANGING ETIOLOGY OF LIVER ABSCESS.
FURTHER OBSERVATIONS. *(E.)* de la Maza,
M.; Naeim, F.; Berman, L. D. (Mallory Inst. Path-
., Boston, Mass.). *JAMA* 227(2):161-163, 1974.

e incidence of liver abscess discovered at autopsy
the Mallory Institute of Pathology has remained
irly constant over the past 70 years (0.57%). The
uses, however, are changing. In a review of 55
ses over the period 1959 through 1968, it was dis-
vered that (1) the incidence of liver abscess
condary to acute appendicitis decreased, but liver
scess secondary to biliary obstruction from chole-
thiasis or carcinoma increased, and (2) the percen-
ge of abscesses associated with Gram-negative bac-
ria has increased steadily since the introduction
antibiotics. The continuous increase in the
thogenic role of enteric organisms was largely due
Kiebsiella-Enterobacter, *Pseudomonas aeruginosa*,
l *Proteus*, although there was also an increase in
croaerophilic and group-D streptococci. Of the
cases, the correct diagnosis was made in only
%. Cholelithiasis was present in 62% of the cases.

3138 FATTY METAMORPHOSIS OF THE LIVER IN MORBID OBESITY. *(E.)* Kern, W. H.; Heger, A. H.; Payne, J. H.; DeWind, L. T. (Univ. Southern California Sch. Med., Los Angeles). *Arch. Pathol.* 96(5):342-346, 1973.

Liver biopsy specimens, obtained from 151 patients at the time of small-bowel bypass procedures for morbid obesity, were reviewed and classified according to degree of fatty metamorphosis, distribution of fatty changes, and presence of inflammation or fibrosis. Some degree of fatty metamorphosis was found in 94% of the patients, and 34% of the patients over half of the hepatic cells were involved. The changes were more severe in patients weighing over 135 kg and in males, but were unrelated to the patient's age. In 88 of 151 cases, there was slight inflammation, and in 42 cases there was slight periportal fibrosis. In 3 cases, fibrosis was consistent with early cirrhosis, and in 3 others, the pattern was characteristic of Laennec's cirrhosis. The findings suggest that the fatty metamorphosis of obesity may proceed to cirrhosis.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

8 CLINICAL IMPLICATIONS OF BILIRUBIN-ALBUMIN BINDING IN THE NEWBORN. *(E.)* Schiff,
Chan, G.; Stern, L. (Dept. Pediatrics, Univ.
erta, Edmonton, Canada). *Rev. Can. Biol.* 32:135-
, 1973.

ee methods of measuring bilirubin-albumin binding
e assessed: analysis of spectral curves; the pheno-
phophtalein or [2-(4'-hydroxybenzeneazo) benzoic
d] dye techniques; and the Sephadex G-25 gel
tration method. The latter two methods were com-
ed using sodium oleate as the competing anion. The
ults suggest that reserve albumin binding capacity,
measured by the dye techniques, is nonspecific for
irubin or any of its competing anions, and thus
ses a question relating to the interpretation of
ults obtained by the reserve albumin binding method
the clinical situation. The presence or absence of
e bilirubin in icteric sera as determined by the
hadex G-25 technique would be more meaningful in the
management of hyperbilirubinemia. In addition to
fisoxazole, salicylate, caffeine, sodium benzoate,
butamide, diazepam, furosemide, oxacillin, hydrocortisone, gentamicin, sodium meralluride, and sulfadiazine displace bilirubin from albumin. Assessment of a drug's bilirubin-albumin binding displacement properties should be included in the overall evaluation of the drug's efficacy and safety.

3179 PHOTOTHERAPY FOR HYPERBILIRUBINAEMIA IN LOW BIRTHWEIGHT INFANTS. *(E.)* Elliott, E.; Moncrieff, M. W.; George, W. H. S. (Derbyshire Children's Hosp., Derby, England). *Arch. Dis. Child.* 49(1):60-62, 1974.

Phototherapy was given to 88 babies whose birthweights were 1500-2500 g and whose serum bilirubin reached 10 mg/100 ml. Alternate babies were treated with 4000-5000 lux for a mean of 62 hr (range 24-168 hr); control cases were not treated unless bilirubin exceeded 15 mg/100 ml. No baby in the treated group developed a bilirubin above 15 mg/100 ml compared with 44% of the control cases. Despite phototherapy at the latter stage, the bilirubin in 3 (8%) of these babies reached 18 mg/100 ml but then fell rapidly.

No side effects occurred apart from overheating in a few babies. The results indicate that phototherapy is a safe and effective way of treating hyperbilirubinemia in low birthweight infants. To avoid unnecessary treatment, therapy should be started when bilirubin reaches 12 mg/100 ml, except for babies under 1500 g when it should be started at 10 mg/100 ml.

Nonviral Hepatitis and Hepatic Injury

3183 JAUNDICE AFTER REPEATED EXPOSURE TO HALOTHANE: AN ANALYSIS OF REPORTS TO THE COMMITTEE ON SAFETY OF MEDICINES. *(E.)* Inman, W. H. W.; Mushin, W. W. (Committee Safety Med., London, England). *Br. Med. J.* 1(5896):5-10, 1974.

In an attempt to identify one or more of the factors associated with jaundice following exposure to halothane or other anesthetic vapors, data derived from 130 reports of jaundice occurring after anesthesia with halothane were analyzed. Jaundice occurred in 20 patients within 28 days of a single exposure to halothane, while 49 additional patients became jaundiced within 20 days of a second exposure to halothane. In the second group, the interval between halothane exposures was 28 days or less in 80% of the cases. Twenty-nine patients became jaundiced after three exposures to halothane; the interval between the first and third exposures to halothane was 14 days to 5 yr, while the interval between the third exposure and the onset of jaundice was 1 to 25 days. Sixteen patients became jaundiced after 4 to 6 exposures to halothane. The interval between the first and last exposure ranged from 16 days to 3.5 years and the interval between the last exposure and the onset of jaundice was 3 to 12 days. Among a group of 16 patients who had been exposed to halothane an unspecified number of times, jaundice developed within 28 days of the last exposure. The mean interval between the last exposure to halothane and the onset of jaundice was significantly shorter for patients exposed 2 or more times than for those exposed only once. In multiple exposure cases, the interval between the most recent exposure and the onset of jaundice did not appear to depend on the length of the period between exposures. Thus repeated exposure to halothane, especially within a short period of time, increases the incidence of jaundice, and this in turn may be fatal. Of the 66 patients whose deaths were attributed to jaundice 59 had two or more exposures to halothane.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

3188 PLASMA EXCHANGE IN PATIENTS WITH FULMINANT HEPATIC FAILURE. *(E.)* Buckner, C. D.; Clift, R. A.; Volwiler, W.; Donohue, D. M.; Burnell, J. M.; Saunders, F. C.; Thomas, E. D. (Univ. Washington Sch. Med., Seattle). *Arch. Intern. Med.* 132(4):487-492, 1973.

Four patients with fulminant hepatic necrosis and oma were treated with 10-liter plasma exchanges aily for 3 to 36 days. Three of these patients ecovered, and two developed acute pulmonary edema ot attributable to volume overload on 2 and 4 ccasions during or following exchange. One of the urviving patients was in a coma for 37 days. During the 12-16 month follow-up period, all of the 3 urviving patients showed evidence of further active epatic disease. In two, this was a single mild pisode 17 and 56 days after plasma exchange. In he third patient, who has been followed for 27 onths, there have been continuing episodes of mild, ctive hepatitis.

189 MULTIVARIATE ANALYSIS OF SERUM PROTEIN ASSAYS IN CHRONIC HEPATITIS AND POSTNECROTIC IRRHOSIS.

(E.) Agostoni, A.; Marasini, B.; Stabiini, R.; Del Ninno E.; Pontello, M. (Inst. Med. athol., Milan, Italy). *Clin. Chem.* 20(4):428-429, 974.

re-albumin, albumin, orosomucoid, α-antirypsin, α-acroglobulin, β_{1A}-globulin, IgG, IgA, and IgM were easured by radial immunodiffusion in the serum of atients with chronic persistent hepatitis (29), ronic aggressive hepatitis (40), and postnecrotic irrhosis (29). Multivariate analysis of the data dicated that by measuring pre-albumin, albumin, d IgA in serum, chronic aggressive hepatitis and stnecrotic cirrhosis can be differentiated in 89% cases. A similar percentage was obtained with bumin, orosomucoid, and IgA, or with albumin, $_{A}$-globulin, and IgA. Discrimination based on the immunoglobulins distinguished chronic aggressive epatitis from chronic persistent hepatitis, but the umber of misclassifications was greater (23%) than the other group.

90 ABNORMAL SERUM LIPOPROTEINS IN CHOLESTATIC VIRAL HEPATITIS.

(Fr.) Picard, J.; issiere, D.; Bertrand, F. (St. Antoine Fac. Med., ris, France). *Clin. Chim. Acta* 51(1):5-12, 1974.

poproteins in serum from 30 patients with persisnt viral hepatitis and total biliary obstruction re separated by centrifugation and gel filtration. stralia antigen was present in only 40% of the paents. The relative proportions of lipid and proin components differed from those found in other ses of cholestasis. The protein ratio was ineased (20% of the micellar weight), while the ospholipid ratio was decreased (31% of the micellar ight). Cholesterol was the major constituent of ese abnormal lipoproteins (57% of the micellar ight), and 90% of the total cholesterol was prest in unesterified form. The lipoproteins had the me immunological properties as previously separed abnormal lipoproteins, as well as the same angenic characteristics caused by the presence of and C apolipopeptides and albumin. The latter mponent represented only 10-15% of the protein iety. The occurrence of at least 2 variants of normal lipoproteins was established by using the me fractionation procedure. The presence of abrmal lipoproteins in the serum of patients with lestatic viral hepatitis is associated with a significant decrease in both α-lipoproteins and β-lipoproteins. These abnormalities demonstrate the impaired synthesis of lipoproteins in these patients with hepatitis.

3191 RELATION OF ALPHA-FETOPROTEIN IN ACUTE HEPATITIS TO SEVERITY AND PROGNOSIS.

(E.) Karvountzis, G. G.; Redeker, A. G. (Univ. Southern California Sch. Med., Los Angeles). *Ann. Intern. Med.* 80(2):156-160, 1974.

Sera from 104 patients with acute viral hepatitis of variable severity were tested for α-fetoprotein by counterelectrophoresis. Among 51 patients with fulminant hepatitis and coma, α-fetoprotein was detected in 17 (85%) of 20 who survived and in only 12 (38.7%) of 31 fatal cases. Among 53 patients without coma, α-fetoprotein was detected in 16. In nonfatal fulminant hepatitis, the frequency of α-fetoprotein positivity increased with increasing duration of coma: in specimens obtained during days 1 and 2 of coma, α-fetoprotein was found in 5 of 13, but when coma persisted for more than 4 days, α-fetoprotein was present in all 11 patients. In the fatal cases of fulminant hepatitis, the frequency of α-fetoprotein positivity was not related to duration of coma. Among the patients with nonfulminant hepatitis, α-fetoprotein was distinctly correlated with the severity of the hepatitis: it was found in 77% of patients with prothrombin levels less than 20% and in only 4.3% of patients in whom prothrombin levels were never less than 60%. The detection of α-fetoprotein in the 16 patients with nonfulminant hepatitis was invariably followed by recovery without progression to hepatic failure, despite the low prothrombin levels or the presence of ascites. The high levels of α-fetoprotein observed in severe forms of hepatitis apparently reflected rapid liver cell regeneration following extensive hepatic necrosis. Sensitive means of assessing regenerative activity during coma would be of prognostic value and useful in the management of acute hepatic failure by radical measures such as hepatic transplantation.

3192 EXCHANGE TRANSFUSION IN THE TREATMENT OF ACUTE SEVERE LIVER FAILURE (WITH HEPATIC COMA) DEVELOPING IN VIRAL HEPATITIS. (EXPERIENCE WITH 80 PATIENTS, 42 OF WHOM WERE GIVEN EXCHANGE TRANSFUSIONS).

(Rum.) Voiculescu, M.; Paun, L.; Dancu, I.; Pavlovici, M. (no affil.). *Med. Interna (Bucur.)* 25(8):981-991, 1973.

Of 80 patients (40 men and 40 women) who developed fulminating liver failure and stage III or IV hepatic coma during viral hepatitis, 38 received standard therapy consisting of glucose infusions, injections of vitamin B complex and vitamin K_1, neomycin (1.4 g p.o.), and hydrocortisone hemisuccinate infusions (600-800 mg/day i.v.). In addition, the remaining 42 patients received exchange transfusions. All but 11 of these patients were under 45 yr old. Exchange transfusions were performed with matched citrated blood by exchanging 5 liters every 2-3 hr so that a total of 20 liters were used. In this way, 60-70% of the circulating blood was replaced. For every 500 ml of blood, one vial of calcium gluconate was administered. Of these 80 patients, 18 (22.5%) recovered: 12 of the 42 (28.5%) given both standard therapy and exchange transfusions and 6 of the 38 (16%) given standard therapy alone. The mean survival time was 3 days 2 hr among those given standard therapy and 4 days 10 hr among those receiving both standard therapy and exchange transfusions. The recovery rate was highest among patients aged 15-30 (15 of 52), among those who developed hepatic coma during the first 7 days after the onset of jaundice (17 of 62), and among those who had prothrombin levels of 30-50% (3 of 3). Because of its effectiveness and simplicity, exchange transfusion is recommended for the treatment of fulminating liver failure and hepatic coma.

3193 THE DISTRIBUTION OF SUBTYPES IN VARIOUS SWEDISH POPULATIONS POSITIVE FOR HEPATITIS B ANTIGEN. *(E.)* Nordenfelt, E.; Le Bouvier, G. (Dept. Med. Microbiol., Univ. Lund, Sweden). *Scand. J. Infect. Dis.* 5(4):279-283, 1973.

Sera from 7 populations positive for hepatitis B antigen (HBAg) were investigated with respect to their antigenic subspecifities. With 2 exceptions, sera from 32 patients, 4 relatives, and 7 staff members infected in epidemics at 2 dialysis units were associated with HBAg (Y) and by inference with hepatitis B virus of subtype Y. The same subtype was found among 10 addicts and 88 of 104 patients with acute hepatitis. Subtype D was predominant among blood donors (10 of 13), and was the only type found among 43 mentally retarded patients and 5 patients who became infected in an epidemic at a home for the aged. Of 5 adopted children, 2 from Korea were carrying HBAg (D) and 3 from India, HBAg (Y). These findings confirm earlier investigations showing that both D and Y subtypes are found in Western societies, but with uneven distribution, reflecting the epidemic and endemic spread of the different genotypes of hepatitis virus. Of potential epidemiological interest is the finding of a new HBAg variant carrying both D and Y specificities on the same particles. This antigen was found in serum from a mentally retarded 49-yr-old male patient. Of 35 sera tested with respect to w and r, 33 were w+. The 2 r+ sera belonged to the 2 adopted Korean children.

3194 A STUDY OF THE RELATIONSHIP OF VIRUS-LIKE PARTICLES AND AUSTRALIA ANTIGEN IN LIVER. *(E.)* Huang, S. N.; Groh, V.; Beaudoin, J. G.; Dauphinee, W. D.; Gutterman, R. D.; Morehouse, D. D.; Aronoff, A.; Gault, H. (Roy. Victoria Hosp., Montreal, Canada). *Hum. Pathol.* 5(2):209-222, 1974.

The ultrastructural and antigenic characteristics of Australia antigen (HBAg)-associated liver particles and their relation to serum HBAg were studied. Liver tissues were obtained from 29 patients with type B hepatitis. Of these patients 17 were renal tranplant recipients with chronic liver disease; all had persistent Australia antigenemia. The remaining 12 patients had acute viral hepatitis (6), chronic active hepatitis (3), and malignant lymphoma and chronic active hepatitis (3). Electron microscopy showed characteristic noncoated virus-like particles in liver cell nuclei in all cases. In some cases, such as renal transplant recipients with chronic active hepatitis, aggregates of the intranuclear particles caused rarefaction of the nucleoplasm. By contrast, only a few particles were seen in liver cell nucleus in patients with acute viral hepatitis. The noncoated particles were also present in the cytoplasm of liver cells from renal transplant patients. In 21 cases liver cells showed marked proliferation of smooth surfaced endoplasmic reticulum, the cisternae of which contained coated particles morphologically identical to Dane particles in serum. In addition, the cisternae of the endoplasmic reticulum contained peculiar filaments and their probable cross sections with an owl eye appearance. The outer covering of the coated particles was continuous with the filaments, suggesting the latter were the crystalloid coat material. Phosphotungstic acid negative stain of liver tissue homogenates and fractionates provided an intermediate linkage in morphological interpretation of tissue and smear findings. Evidence indicated the hepatic origin of the HBAg particles. Immunoagglutination electron microscopy confirmed that HBAg particles in tissue homogenates and sera were antigenically identical; the noncoated particle although morphologically similar to the core component of Dane particles, appeared antigenically different from HBAg coat material. These observations support the concept that Dane particles have dual antigenic specificities. Pure core particles were absent in serum, and it is suggested that these particles are released in clusters that are readily phagocytosed by leucocytes.

3195 SERUM ALPHA-FETOPROTEIN LEVELS IN ACUTE VIRAL HEPATITIS. *(E.)* Kew, M. C.; Purves, L. R.; Bersohn, I. (Dept. Med. Univ. Witwatersrand, South Africa). *Gut* 14(12):939-942, 1973.

Serum α-fetoprotein levels were measured serially by radioimmunoassay in 28 black and 4 white patients (17 males, 15 females; aged 4 months to 43 yr) with acute viral hepatitis. With 1 exception, the levels were increased during the course of the illness. Raised concentrations of the protein occurred almost equally in patients with and without the hepatitis-B antigen. In the majority of patients the rise was modest but in 7 levels greater than 1000 ng/ml were reached. Six of these 7 patients were under age 12 yr. In 8 patients the concentration increased as the SGPT level, used as an index of hepatocyte damage, was returning to normal, a pattern which favored increased synthesis of the protein during hepatocellular regeneration. In the remainder, the α-fetoprotein level paralleled that of SGPT, suggesting rather an acute-phase reaction to liver injury.

3196 A STUDY OF HEPATIC DISEASE IN AUSTRALIA ANTIGEN AND ANTIBODY-POSITIVE BLOOD DONORS. *(E.)* Russell, R. I.; Goldberg, D. M.; Allan, J. G.; MacSween, R. N. M.; Wallace, J. (Roy. Infirm., Glasgow, Scotland). *Am. J. Dig. Dis.* 19(2):113-121, 1974.

 total of 39 blood donors (28 males and 11 females)
ound on routine testing to be Australia antigen
HB Ag) or antibody (HB Ab) positive, were studied
or evidence of hepatic disease. Seven had severe
nd 5 had minor biochemical abnormalities which were
estricted to serum enzymes, notably isocitrate de-
ydrogenase, glutamate dehydrogenase, adenosine dea-
inase, guanase, and SGOT; 8 of these 12 subjects had
B Ag and 4 HB Ab. Four had serum cholesterol eleva-
ions but no other biochemical abnormalities. In 23
ubjects biochemistry was normal. Of 11 subjects who
nderwent hepatic biopsy, 3 were found to have evid-
nce of chronic persistent hepatitis. Two of these
 had HB Ag and 1 had HB Ab. Although 2 of the 3 had
evere biochemical abnormalities, 1 had normal bio-
hemistry. Minor histological abnormalities were
ound in 4 other donors without biochemical abnor-
alities. The results suggest that subjects with
ersistently positive tests for HB Ag or HB Ab may
ave chronic hepatic disease. Close follow-up
 blood donors and other subjects found to have
ositive tests is thus indicated. Normal biochemical
indings do not exclude abnormal hepatic histology.

LIVER AND BILIARY TRACT

Chronic Hepatitis

3214 TREATMENT OF ACTIVE CHRONIC HEPATITIS WITH CYCLOPHOSPHAMIDE. *(E.)* Naccarato, R.; Farini, R.; Chiaramonte, M.; Fagiolo, U.; Sturniolo, G. C. (Inst. Med. Pathol., Univ. Padua, Italy). *Postgrad. Med. J.* 50:16-24, 1974.

Clinical, biochemical, and immunological changes in 20 patients with active chronic hepatitis were observed during and after treatment with cyclophosphamide and/or corticosteroids. One group of 10 patients received cyclophosphamide alone (200 mg/day i.v. for a total of 5-6 g followed, after a 1-3 months discontinuation of treatment, by 100-150 mg/day p.o. or i.v. for a total of 4-5 g). A second group of 4 patients was treated with cyclophosphamide after prednisolone therapy (15-20 mg/day for 2-3 months). A third group of 6 patients received only corticosteroid therapy (15-20 mg/day prednisolone or 16-24 mg/day triamcinolone in 2-3 month cycles). In the 3 groups of patients there was a gradual decrease in asthenia and dyspepsia, a decrease or disappearance of arthromyalgia, and a return to normal of bowel movements and diuresis. The improvement was greatest in patients treated with cyclophosphamide alone. Patients treated with cyclophosphamide showed swift regression or disappearance or jaundice within the first month of treatment, while in the other two groups this decrease was slower or absent. In the cyclophosphamide group, total serum bilirubin, SGOT, SGPT, and serum ornithine carbamyl transferase normalized within 2 months after the institution of treatment. Blood albumin and gamma-globulin levels and some immunological findings (serum immunoglobulins, serum antismooth muscle, antiglomerular basal membrane, and antigamma-globulin) showed periodic variations during the course of the disease in all 3 groups. Serum mitochondrial antibodies disappeared from blood in all patients treated with cyclophosphamide. Cyclophosphamide gave the best results in patients with chronic aggressive hepatitis type A. The histological picture remained unchanged after treatment.

3215 HEPATOGRAPHY PATTERNS FOLLOWING RECTAL ADMINISTRATION OF RADIOIODINE AS SEEN IN CHRONIC LIVER DISEASE AND OTHER LIVER DISORDERS. *(E.)* Steinberg, M.; Marner, I.-L.; Waever Rasmussen, J. (Odense Univ. Hosp., Denmark). *Scand. J. Gastroenterol.* 9(1):73-79, 1974.

Following rectal instillation of ^{131}I-labeled NaI (40 µCi), liver and plasma activity-time curves were analyzed in 38 patients. Of these patients, 10 were normal controls, 18 had chronic liver disease, 6 had liver metastases, and 4 had miscellaneous liver abnormalities. Two basic hepatography patterns were found. Type I, seen in all normal controls, indicates direct rectum to liver blood flow *via* the portal vein. Type II represents portal-systemic collateral blood flow and was seen in 9 of the 18 patients with chronic liver disease. Of the patients with liver metastases, Type I was seen in 3 cases, a varient of Type I in 2 cases, and Type II in a single case. The results indicate that hepatography is useful in demonstrating portal hypertension, but is of little value in the study of liver metastases.

3216 CHRONIC LIVER DISEASE: DIFFERENCES IN AUT IMMUNE SEROLOGICAL REACTIONS BETWEEN AUSTR LIANS AND ASIANS. *(E.)* Whittingham, S.; Mackay, I. R.; Thanabalasundrum, R. S.; Chuttani, H. K.; Manjuran, R.; Seah, C. S.; Yu, M.; Viranuvatti, V. (Roy. Melbourne Hosp., Victoria, Australia). *Br. Med. J.* 4:517-519, 1973.

A serological study of 164 patients with chronic liver disease from Australia, Ceylon, India, Singapore, and Thailand is described. There is a high prevalence of autoantibodies associated with chronic idiopathic liver disease among Australians (55%) com pared with those from the Asian countries (0-14%). The levels of these autoantibodies were also high among Australians in that antinuclear antibodies ranged up to 167 u/ml and smooth muscle antibodies up to a titer of 512; the maximum level of antinuclear antibodies among the Asian patients was 167 u/ml and the highest titer of smooth muscle antibodi was 128. In none of the groups was there a high prevalence of hepatitis B antigen. The main explana tions for differences in prevalence and type of liver diseases among racial groups would include differing exposure or susceptibility to infectious agents or toxic agents, nutritional differences, and inter-racial genetic differences. Genetic differences expressed through histocompatibility antigens could be a factor accounting for differences in racial prevalence of disease in general, and for the autoimmune type of active chronic hepatitis in particular.

3217 THE ULTRASTRUCTURE OF AUSTRALIA ANTIGEN IN THE PRESENCE AND THE ABSENCE OF SPECIFIC ANTIBODIES. *(E.)* Muscatello, U.; Bianchi, F. B.; Pisi, E. (Inst. Gen. Pathol., Univ. Modena, Italy). *Br. J. Exp. Pathol.* 54(6):658-664, 1973.

The technical conditions which allow high resolution electron microscopy of Australia (Au) antigen were investigated. Reliable and consistent results were btained using uranyl acetate as the negative stain, t pH 4.5 Au antigen may have a tubular or 2 round orms. Tubular forms vary in length from 40-400 nm ut have a constant diameter of about 21 nm. The ound forms are distinguished on the basis of their ean diameter, smaller forms having a mean diameter f 21 nm and large forms, a diameter of 42 nm. The maller round forms apparently derive from the tubular orms through a process of terminal splitting; the arger forms may originate from the same tubular orms through a process involving a complicated rerrangement of structural subunits. In the absence f antibody, Au subunits are regularly arranged in a elical lattice, as shown by the image analysis obained by optical diffraction. After reaction with pecific antibody, the geometry of the lattice is ess evident or even totally obscured due to the resence of material attached to the particle surace. This material consists of antibody molecules aving the dimensions and shape typical of IgG. At igher antibody concentrations, clumps of antigen articles are formed. It is suggested that changes n the elementary structure of subunits be used as marker for the existence of an antigen-antibody eaction. The formation of clumps is a less reliable arker because of the occurrence of nonspecific gglutination with the negative staining procedure. u antigen particles prepared from the sera of 5 atients with chronic hepatitis had antibodies bound o their surface. Whether this is a consistent feaure of active chronic hepatitis is not clear at resent.

218 ANTICOMPLEMENTARY HEPATITIS B ANTIGEN. *(E.)* Gitnick, G. L.; Summerskill, W. H. J.; Soloway, R. D.; Ritman, S.; Schoenfield, L. J. (Dept. ed. UCLA Ctr. Health Sci., Los Angeles, Calif.). rch. *Intern. Med.* 132(4):502-505, 1973.

The prognostic importance of anticomplementary hepatitis B antigen (HB Ag) tests was assessed in 63 patients with chronic active liver disease in a prospective controlled treatment trial. The patients were randomly assigned to groups receiving placebo, prednisone (60 mg/day for 4 weeks, then 20 mg/day), azathioprine (100 mg/day), or a combination of prednisone (10 mg/day) and azathioprine (50 mg/day). A positive result was correlated with poor prognosis and failure of treatment in 11 of 18 patients receiving placebo or azathioprine. In contrast, marked improvement in prognosis occurred in 12 of 14 patients receiving prednisone or the prednisone-azathioprine combination. Patients with anticomplementary assays had a worse prognosis than did those whose sera were either HB Ag-positive or HB Ag-negative. Lupus erythematosus and smooth muscle antibody tests did not distinguish subgroups or influence response to treatment or prognosis. Among patients with chronic active liver disease, an anticomplementary assay indicates a more urgent need for prednisone treatment.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

3223 VITAMIN B_6 METABOLISM IN CHRONIC ALCOHOL ABUSE: PYRIDOXAL PHOSPHATE LEVELS IN PLASMA AND THE EFFECTS OF ACETALDEHYDE ON PYRIDOXAL PHOSPHATE SYNTHESIS AND DEGRADATION IN HUMAN ERYTHROCYTES. *(E.)* Lumeng, L.; Li, T.-K. (Indiana Univ. Sch. Med., Indianapolis). *J. Clin. Invest.* 53(3): 693-704, 1974.

Vitamin B_6 metabolism in chronic alcoholic abuse was studied by comparing plasma pyridoxal-5'-phosphate (PLP) levels in 66 male alcoholics (aged 18-68 yr) with those of 99 healthy male controls. All the alcoholics were free of hematologic and liver disorders. In controls plasma PLP concentrations ranged from 5 to 26.3 ng/ml. The range for the alcoholic group was 1.9 to 13.1 ng/ml, with 35 subjects having plasma PLP values below 5 ng/ml. These data indicate a high incidence of deranged PLP metabolism in alcoholic patients even when hepatic and hematologic abnormalities are absent. Low plasma PLP levels in alcoholics were not accompanied by decreased pyridoxal kinase and pyridoxine phosphate oxidase activities in erythrocytes. Further studies with erythrocytes demonstrated that the cellular content of PLP is determined not only by the activities of these PLP-synthesizing enzymes but also by the activity of a phosphate-sensitive, membrane-associated, neutral phosphatase which hydrolyzes phosphorylated vitamin B_6 metabolites. Acetaldehyde (0.05-1 mM), but not ethanol (to 70 mM), impaired the net formation of PLP from pyridoxal, pyridoxine, and pyridoxine phosphate by erythrocytes. This effect of acetaldehyde was abolished when the B_6-phosphate phosphatase activity was inhibited by 80 mM phosphate. Experiments with broken cell preparations confirmed that the action of acetaldehyde is mediated by the phosphatase, resulting in accelerated degradation of the phosphorylated vitamin B_6 metabolites in erythrocytes.

3224 LIVER LIPID CONTENT IN ALCOHOLICS. *(E.)* Lundquist, A.; Wiebe, T.; Belfrage, P. (Univ. Hosp., Lund, Sweden). *Acta Med. Scand.* 194(6):501-504, 1973.

Liver biopsy specimens from 51 alcoholics (49 males and 2 females, aged 48 ± 11 yr) obtained with a 0.7 mm needle have been analyzed for lipid content and these values have been compared with the evaluation of visible fat in smears from the same biopsy specimens. Large variations in liver lipid concentrations have been found, ranging from one group, 24% of total, with fat within normal limits to a few individuals with a 100-fold increase in liver lipid concentration. This variation is partly explained by varying abstinence times before biopsy. Morphologically liver lipid levels were classified from 0 to 3; 0 indicating no or only a few small vacuoles, 1 indicating small vacuoles in a minority of the cells, 2 indicating small or large vacuoles in a majority of the cells, and 3 indicating small and/or large vacuoles in almost every hepatocyte. For routine purposes, this classification of liver fat in fine-needle biopsy specimens allows adequate estimation of liver lipid levels. Serum transaminases and bilirubin were the only laboratory data found to co-vary with liver fat.

3225 ISOENZYME PATTERNS OF SERUM ALKALINE PHOSPHATASE IN ETHANOL-INDUCED LIVER INJURY. *(E.)* Brohult, J.; Sundblad, L. (Med. Dept. IV., Sodersjukhuset, Stockholm, Sweden). *Acta Med. Scand.* 194(6):497-499, 1973.

Abnormal agar gel electrophoretic patterns of alkaline phosphatase isoenzymes have been demonstrated in 11 out of 16 male chronic alcoholics (aged 35-60 yr) in spite of normal or borderline routine liver tests including total alkaline phosphatase, SGOT, SGPT, and bilirubin. The abnormality consisted of the presence of a fast-moving alpha$_1$-fraction known to be related to hepatic disease, preferably of an obstructive type. The alpha$_1$-fraction averaged 9.4 U/liter in the 11 cases and constituted 8-24% (mean 13%) of the total alkaline phosphatase activity. The presence of alpha$_1$-alkaline phosphatase appears to be a more sensitive indicator of ethanol-induced liver damage than LDH-5 and ornithine carbamoyl transferase. These results indicate that this test may be a very sensitive aid in diagnosing alcohol abuse. The data reveal that there are stages of ethanol-induced liver involvement when alpha$_1$-alkaline phosphatase and LDH-5 are increased in spite of normal values for other liver function tests.

3226 EFFECTS OF ETHANOL UPON LIPID METABOLISM. *(E.)* Lieber, C. S. (VA Hosp., Bronx, N.Y.). *Lipids* 9(2):103-116, 1974.

LIVER AND BILIARY TRACT

Cirrhosis

3227 HIGH PREVALENCE OF SEROIMMUNOLOGIC ABNORMALITIES IN RELATIVES OF PATIENTS WITH ACTIVE CHRONIC HEPATITIS OR BILIARY CIRRHOSIS. *(E.)* Galbraith, R. M.; Smith, M.; Mackenzie, R. M.; Tee, D. E.; Doniach, D.; Williams, R. (King's Coll. Hosp., London, England). *N. Engl. J. Med.* 290(2):63-69, 1974.

To determine the familial prevalance of serologic abnormalities, immunoglobulin disturbances, and biochemical evidence of liver dysfunction, 260 relatives of patients with chronic hepatitis (24 women and 9 men, aged 13-80 yr) or primary biliary cirrhosis (21 women and 1 man, aged 30-80 yr) were studied. Mitochondrial, smooth-muscle, and nuclear antibodies were more frequent among relatives of these patients than in controls matched for age and sex. Abnormal immunoglobulin levels occurred in almost half the relatives, and 71% had some immunologic disturbance. In addition, elevated alkaline phosphatase levels and hypergammaglobulinemia were common, the latter being more frequent in relatives of patients with chronic hepatitis (34%) than in relatives of patients with biliary cirrhosis (9.3%). Furthermore, in 3 of the 55 families studied, 2 or more members had cirrhosis. These findings suggest a similar genetic predisposition to immunologic abnormalities among the families of patients with these 2 diseases. The translation of such predisposition into clinical liver disease is probably related to environmental factors.

3228 SINUSOIDAL STENOSIS--THE CAUSATIVE ANATOMICAL LESION OF PORTAL HYPERTENSION. *(E.)* Nakata, K.; Uehara, Y.; Wada, K.; Fujimoto, K.; Fujikawa, Y.; Itaya, H. (Osaka Med. Coll., Japan). *Acta Pathol. Jap.* 23(2):225-236, 1973.

To clarify the anatomical lesion responsible for he development of portal hypertension without vasular occlusion, portal pressure measurements in 5 patients were correlated with histological findngs in liver biopsies. The 35 patients consisted f 11 with fibrosis of the liver and 24 with cirhosis. Controls with intact livers included 4 paients with gastric ulcer, 1 with duodenal ulcer, with cholelithiasis, and 5 with gastric cancer ithout hepatic metastasis. Portal venous pressure veraged 328.6 mm H_2O in liver fibrosis and 384 mm $_2O$ in cirrhosis, compared with 108.3 mm H_2O in ontrols. The mean diameter of hepatic cells inreased from a control value of 19.41μ to 22.55μ n fibrosis and 23.24μ in cirrhosis, while the perentage of sinusoidal space within a square unit of iver lobule decreased from 10.66% in controls to .35% and 5.82%, resp., in fibrosis and cirrhosis. here was a close inverse correlation between the egree of sinusoidal stenosis and the portal hyperension. Vascular lesions of both the portal venous ree and the hepatic venous tree were minimal. hese results indicate that sinusoidal stenosis is he most important anatomical lesion leading to ortal hypertension.

229 HYPERDYNAMIC STATES AND THE PHYSIOLOGIC DETERMINANTS OF SURVIVAL IN PATIENTS WITH IRRHOSIS AND PORTAL HYPERTENSION. *(E.)* Seigel, . H.; Goldwyn, R. M.; Farrell, E. J.; Gallin, P.; riedman, H. P. (Buffalo Gen. Hosp., N.Y.). *Arch. urg.* 108(3):282-292, 1974.

he ability of the cirrhotic patient to withstand he acute stress of variceal hemorrhage or necessary ortal decompressive surgery is related to the adeuacy of the cardiovascular and cardiorespiratory inerrelationships. A multivariable statistical analyis of 17 variables in 28 patients with cirrhotic iver disease and 81 controls was performed. Three ifferent hyperdynamic cardiovascular states were ound in the cirrhotic patients: a control hyperynamic state characterized by an increased cardiac utput, without evidence of abnormal peripheral vasular or pulmonary dysfunction; a balanced hyperdynamc response to stress in which a further increase n cardiac output is usually compensated for by an dequate increase in myocardial contractility and xygen consumption; and an unbalanced hyperdynamic tress state in which there is evidence of severe eripheral vascular abnormality, impaired oxygen exraction, and a tendency to the development of highutput cardiac failure. The use of inotropic support n the preoperative or immediated postoperative cirrhotc patient should be considered based on the cardiac ndex, the cardiac mixing time, the arteriovenous xygen gradient, and the ratio of alveolar-arterial xygen gradient and arterial PO_2.

230 TRANSTHORACIC LIGATION OF BLEEDING ESOPHAGEAL VARICES IN PATIENTS WITH INTRAHEPATIC ORTAL OBSTRUCTION. *(E.)* Ottinger, L. W.; Moncure, . C. (Harvard Med. Sch., Boston, Mass.). *Ann. Surg.* 79(1):35-38, 1974.

n a group of 72 patients with intrahepatic portal bstruction undergoing transthoracic ligation of esophageal varices for active hemorrhage as the immediate procedure to control bleeding, the mortality rate was 50%. The success of the procedure in controlling hemorrhage and allowing the patient to come to the definitive portosystemic shunt directly paralleled hepatic functional reserve. Of the 72 patients, 13 were classified as Child Class A patients, (7 with Laennec's and 6 with postnecrotic cirrhosis) for serum bilirubin below 2.0 mgm%, serum albumin over 3.5 gm%, no ascites, no neurological disorder, and excellent nutrition were the prevailing conditions. A further 29 were classed as Class B patients (17 with Laennec's and 12 with postnecrotic cirrhosis) for serum bilirubin 2.0-3.0 mgm%, serum albumin 3.0-3.5 gm%, easily controlled ascites, minimal neurological disorder, and good nutrition were the prevailing conditions. The remaining 30 were classed as Class C patients (20 with Laennec's and 10 with postnecrotic cirrhosis) for serum bilirubin over 3.0 mgm%, serum albumin under 3.0 gm%, poorly controlled ascites, advanced neurological disorders and poor nutrition prevailed. The procedure was uniformly successful in Child Class A patients, 55% successful in Class B patients, and only 10% successful in Class C patients. Of these 72 patients, 9 (12½) developed fistulae from the esophageal suture line. The incidence increased with increasing severity of liver decompensation and the complication was invariably fatal.

3231 TREATMENT OF STABILIZED LIVER CIRRHOSIS BY DEHYDROEPIANDROSTERONE SULPHATE. I. EVALUATION OF PRINCIPAL BIOCHEMICAL TESTS AS A WHOLE. *(E.)* Fassati, P.; Fassati, M.; Sonka, J.; Josifko, M. (Dist. Inst. Pub. Hlth., Prague, Czechoslovakia). *Agressologie* 14(4):259-268, 1973.

Dehydroepiandrosterone sulphate (80 mg/day) for 6 months to 39 patients with stabilized liver cirrhosis led to a significant improvement of the bromsulphalein test, to an elevation of serum albumin and a decrease of globulins, especially gamma-globulin levels, to a reduction of cholesterolemia and beta-lipoproteinemia. The flocculation tests improved or remained unchanged. Both current aminotransferases (SGPT and SGOT) and total serum bilirubin showed an insignificant improvement. The only test which seemed to deteriorate was serum alkaline phosphatase. It is suggested that the favorable effect of dehydroepiandrosterone sulphate used in liver cirrhosis may be due to the metabolic role of this steroid which is a potent inhibitor of glucose-6-phosphate dehydrogenase and 11-beta-hydroxylase. The tendency toward enhanced synthesis of lipids, aldosterone and different proteins found in the chronic inflammatory process of liver injury may be corrected by the resulting metabolic effects.

3232 ESTIMATIONS OF LOBAR HEPATIC BLOOD FLOWS AND EXTRACTIONS IN SEVERE LIVER CIRRHOSIS. *(E.)* Strandell, T.; Erwald, R.; Lundbergh, P.; Wiechel, K. L. (St. Erik's Hosp., Stockholm, Sweden). *Acta Med. Scand.* 194(3):219-220, 1973.

A technique for the determination of the various hepatic blood flows in patients with advanced liver cirrhosis is presented. The material comprised 1 female alcoholic with severe liver cirrhosis, ascites, and moderate jaundice. A large outer catheter was inserted in the umbilical vein to the distal end of the left portal branch. Within this outer catheter a 2.0/2.5 mm wide teflon one was located into the splenic vein. A 1.05/1.40 mm wide fluor-ethylene-propylene spray catheter with occluded end and 4 side holes was also positioned there. The teflon catheter was removed and beside the infusion catheter a 1.0/1.3 mm wide teflon one was introduced. Additional catheters were precutaneously inserted into a peripheral artery, a peripheral vein and a right hepatic vein. Through the spray catheter 0.2-0.5 mC ^{133}Xe in 100 ml physiological saline was repeatedly infused, first into the splenic vein at a rate of 15 ml/min, later at a rate of 27 ml/min into the middle of the main portal trunk and finally into the first part of the left portal branch. During the infusions, airfree blood samples were drawn in duplicate in 2 ml heparinized plastic syringes from the 2 portal branches, the hepatic veins, and the peripheral artery. The ^{133}Xe activity in the blood samples was measured. The left portal branch contributed 47% of total portal venous flow in the cirrhotic patient compared to 24 and 22%, respectively in the 2 others without signs of liver cirrhosis. In the cirrhotic patient the hepatic artery contribution was 36% in the right lobe, 37 and 34% respectively, in the 2 veins, but 68% in the left lobe. In the other 2 patients, the hepatic artery flows were 41 and 20%, respectively, of total hepatic flow. It is concluded that this method permits a detailed analysis of the complex hepatic circulation in the cirrhotic patient.

3233 SURVIVAL PREDICTION IN PORTACAVAL SHUNTS: A COMPUTERIZED STATISTICAL ANALYSIS. *(E.)* Campbell, D. P.; Parker, D. E.; Anagnostopoulos, C. E. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Am. J. Surg.* 126(6):748-751, 1973.

A computerized statistical analysis of survival prediction in portacaval shunts based on Child's criteria is presented. The material includes 50 patients who underwent end to side portacaval shunts. All patients were assigned to one of Child's groups according to the degree of hepatic functional reserve. Child's criteria measure serum bilirubin, serum albumin, ascites, neurological disorder, and nutrition. Eighteen patients were classified as good risks (Child's A, good hepatic function); 17 patients (38%) were classified as fair risks (Child's B, moderately impaired hepatic function); 10 patients (22%) were classified as poor risks (Child's C, advanced hepatic dysfunction. A decision was reached in 62% of the patients studied, that is, 62% of the patients fell into Child's criteria A or C. Of the 28 subjects for whom a decision was made, 23 were correctly classified and 5 were not. Thus, 59% of the postshunt short-term (18 months or less) and long-term (42 months or more) survivors were correctly identified by the use of Child's criteria. The ability of Child's criteria to correctly identify the long- and short-term survivors was much more accurate for the postnecrotic group than for the nutritional groups. The results confirm that Child's criteria are as good a set of easily obtained predictive parameters as is presently available.

3234 CIRRHOSIS AND HETEROZYGOUS FZ α_1-ANTITRYPSIN DEFICIENCY IN AN ADULT. CASE REPORT AND REVIEW OF THE LITERATURE. *(E.)* Brand, B.; Bezahler, G. H.; Gould, B. (Montefiore Hosp. Med. Ctr., Bronx, N.Y.). *Gastroenterology* 66(2):264-268, 1974.

A case report is presented of a 78-year-old woman without clinical pulmonary disease, and with unsuspected α_1-antitrypsin deficiency who was found to have eosinophilic, periodic acid Schiff-positive, diastase-resistant cytoplasmic inclusions, and cirrhosis, on liver biopsy. Physical examination on admission revealed an elderly woman with obvious orthopnea. Pertinent laboratory data revealed hemoglobin 11.6 g, white blood count 7200; serum glutamic oxaloacetic transaminase 54 mU/ml, alkaline phosphatase 99 mU/ml, cholesterol 133 mg/100 ml, lactic dehydrogenase 225 mU/ml, total bilirubin 0.9 mg/100 ml, protine 12/12, total protein 6.5 g/100 ml, albumin 2.8 g/100 ml. Chest X-ray revealed cardiomegaly and a prominent pulmonary venous pattern without evidence of emphysema or chronic lung disease. Electrocardiogram revealed an old anterior wall myocardial infarction and atrial fibrillation. Liver scan showed hepatosplenomegaly with patchy hepatic uptake. Microscopic sections of the liver biopsy showed fragmentation of the specimen and replacement of the hepatic lobular architecture by micro- and macronodules separated by fibrous septae of varying thickness. Serum protein electrophoresis revealed an α_1-globulin of 2.0% (128 mg/100 ml), α_2-globulin of 12%, β-globulin of 17%, and γ-globulin of 27%. Because of the low α_1-globulin and liver biopsy findings, phenotyping for α_1-AT deficiency was performed. Her phenotype revealed a protease inhibitor Pi^{FZ} pattern and serum trypsin-inhibiting capacity was 0.827 U. It is concluded that a search for α_1-antrypsin deficiency should be carried out in all cases of cryptogenic cirrhosis, regardless of age.

3235 "IDIOPATHIC" PORTAL HYPERTENSION DUE TO OCCLUSION OF INTRAHEPATIC PORTAL VEINS BY ORGANIZED THROMBI: A STUDY BASED ON POSTMORTEM VINYLITE-INJECTION CORROSION AND DISSECTION OF THE INTRAHEPATIC VASCULATURE IN 4 CASES. *(E.)* Boyer, J. L.; Hales, M. R.; Klatskin, G. (Yale Univ. Sch. Med., New Haven, Conn.). *Medicine* 53(1):77-91, 1974.

Four cases of severe portal hypertension with splenomegaly and esophageal varices are presented. The portal hypertension was designated idiopathic in that its cause was not apparent after surgical wedge biopsies of the liver, portography, and measurement of the wedge hepatic vein pressure. However, postmortem investigation of the intrahepatic vasculature by vinylite-injection corrosion in 3 cases and by dissection in 1 case revealed extensive attenuation and occlusion of the intrahepatic portal vein branches by organized thrombi. These observations together with previously reported data suggest that many cases of idiopathic portal hypertension are due to occlusion of the intrahepatic portal vein radicles by organized thrombi, and that currently available diagnostic techniques may fail to detect such vascular lesions during life.

3236 HEPATIC ARTERIALIZATION AND PORTACAVAL SHUNT IN HEPATIC CIRRHOSIS: AN ASSESSMENT. *(E.)* Maillard, J. N.; Rueff, B.; Prandi, D.; Sicot, C. (Hosp. Louis Mourier, Colombes, France). *Arch. Surg.* 108(3):315-320, 1974.

A survey of the results obtained by four teams of workers shows that hepatic arterialization has usually been combined with elective end-to-side portacaval anastomosis (PCA); in some patients, however, it has been done for the relief of encephalopathy months or years after PCA, and in other patients it has been associated with emergency PCA. The total hepatic blood flow after PCA plus arterialization with a small-caliber artery is equal to, or slightly greater than, the preshunt flow. After PCA plus arterialization, the immediate postoperative complications are no worse than after PCA alone, but the subsequent incidence of portosystemic encephalopathy is less. The arteriovenous anastomosis itself is unlikely to be permanent. If it remains patent throughout the first postoperative year, which is the most critical phase of the post-shunt course, it will have served a useful purpose.

3237 EMERGENCY PORTACAVAL SHUNT TREATMENT FOR BLEEDING ESOPHAGEAL VARICES. PROSPECTIVE STUDY IN UNSELECTED PATIENTS WITH ALCOHOLIC CIRRHOSIS. *(E.)* Orloff, M. J.; Chandler, J. G.; Charters, III, A. C.; Condon, J. K.; Grambort, D. E.; Modafferi, T. R.; Levin, S. E. (Sch. Med., Univ. California, San Diego). *Arch. Surg.* 108(3):293-299, 1974.

A prospective evaluation of the emergency portacaval shunt was conducted over a 10-yr period in 115 consecutive cases of alcoholic cirrhosis and bleeding esophageal varices. An extensive diagnostic evaluation was completed within 7 hr of hospital admission and the shunt operation was undertaken within a mean of 8.1 hr. Follow-up was conducted in a special clinic and the current status of 98.3% of the patients is known. Eighty-two percent of the patients had jaundice, ascites, or encephalopathy, alone or in combination, upon admission. Contrary to recent proposals, the patients with the highest portal perfusion pressures and the largest hepatopetal portal blood flows had the highest survival rate, and those who sustained the smallest portal flow diversion from the shunt had the lowest survival rate. The operative survival rate for the 115 cases was 48%, the predicted 7-yr survival rate was 30%, and the actual 7-yr survival rate was 42.5%. There was no difference in survival rates between side-to-side and end-to-side portacaval shunts. In comparison with the results of previous prospective studies, emergency portacaval shunt resulted in a significantly greater long-term survival rate than either emergency medical therapy or emergency varix ligation followed by elective shunt.

3238 EXPERIMENTAL STUDY OF HYPERDYNAMIC VS. STAGNANT MESENTERIC BLOOD FLOW IN PORTAL HYPERTENSION. *(E.)* Witte, C. L.; Witte, M. H.; Bair, G.; Mobley, W. P.; Morton, D. (Univ. Arizona Coll. Med., Tucson). *Ann. Surg.* 179(3):304-310, 1974.

The responses of the mesenteric circulation and the thoracic duct lymph circulation were studied in 18 dogs under conditions which reproduced an exclusively stagnant circulation, a hyperdynamic circulation, or a combination of the two. Although acute portal vein constriction (stagnant circulation) produced marked portal hypertension and an increased thoracic duct lymph flow, this maneuver was associated with a pronounced reduction in the mesenteric arterial flow and mesenteric venous blood oxygen saturation and with a sharp rise in mesenteric vascular resistance and splanchnic oxygen extraction. In contrast, the infusion of glucagon (hyperdynamic circulation) at 0.5 ml/min for 60 min (total dose 30 μg/kg) doubled the mesenteric arterial flow with maintenance of high oxygen saturation of the mesenteric venous blood, low mesenteric vascular resistance, and a modest increase in the thoracic duct lymph flow, which was slightly lowered in protein content. The portal pressure was minimally increased. Slight portal vein constriction combined with the infusion of glucagon produced marked portal hypertension with highly oxygenated mesenteric venous blood and a greatly increased thoracic duct lymph flow low in protein. The mesenteric arterial flow was slightly increased and the mesenteric vascular resistance was slightly lowered. The data indicate that increased portal vascular resistance operates in conjunction with increased splanchnic blood flow to produce the clinical patterns of portal hypertension. "Active congestion" rather than "passive congestion" more accurately characterizes the circulatory derangement in human portal hypertension.

3239 ARSENIC AND NONCIRRHOTIC PORTAL HYPERTENSION. *(E.)* Morris, J. S.; Schmid, M.; Newman, S.; Scheuer, P. J.; Sherlock, S. (Roy. Free Hosp., London, England). *Gastroenterology* 66(1): 86-94, 1974.

Portal hypertension occurred in two patients after 3 and 22 years of treatment with Fowler's solution (arsenic trioxide 1%). One patient had taken about 6 g of arsenic and the other had taken 25-29 g. Other side effects die to arsenic ingestion included skin pigmentation, skin tumors, carcinoma of the larynx, and a probable bronchial carcinoma in one patient, and skin pigmentation and keratoses in the other patient. The level of arsenic in the liver of one patient was markedly high (28 μg/g dry liver). Histological examination of the liver in both patients revealed portal tract fibrosis and an increase in the number of portal veins. In one patient there was slight sclerosis around the portal veins, and in the other the portal veins were greatly thickened and had hypertrophic muscular walls. Repeated histological examination of the liver failed to reveal cirrhosis in either patient. In both patients, the intrasplenic vein pressure was high (17 and 30 mm Hg), indicating that the obstruction to portal flow resided in the portal tracts. It is possible that arsenic is an etiological factor in the production of noncirrhotic portal hypertension in some patients, perhaps because of damage to the intrahepatic portal veins.

3261 BILE ACID EXCRETION AFTER DISAPPEARANCE OF JAUNDICE IN INTRAHEPATIC CHOLESTASIS OF INFANCY. *(E.)* Norman, A.; Strandvik, B. (Karolinska Inst., Stockholm, Sweden). *Acta Paediatr. Scand.* 62(3):264-268, 1973.

In 12 cases of intrahepatic cholestasis of infancy the patients were re-examined 1-58 weeks after disappearance of jaundice. All infants were clinically healthy, but 4 showed raised serum transaminase. Cholic acid-24-^{14}C was injected intramuscularly and the isotope excretion in the urine and feces was investigated for 4 days after the injection. Most of the isotope was excreted in the feces. In 5 of the 12 infants the urine contained 9-26% of the administered isotope whereas the other infants excreted less than 5%. No unconjugated labelled cholic acid was excreted. After solvolysis and hydrolysis the major labelled compound was identified as cholic acid. In 7 healthy infants used as controls no cholic and chenodeoxycholic acids were detected in the urine. All the 12 patients excreted cholic and chenodeoxycholic acids in the urine at the time of the re-examination, the total daily urinary excretion ranging from 0.6 to 3.7 μmol. These results indicated that the bile acid excretion was still impaired after regression of jaundice in the infants who had had intrahepatic cholestasis.

GENERAL

3301 PROTEIN NUTRITION AND LIVER DISEASE AFTER JEJUNOILEAL BYPASS FOR MORBID OBESITY. *(E.)* Moxley, III, R. T.; Pozefsky, T.; Lockwood, D. H. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *N. Engl. J. Med.* 290(17):921-926, 1974.

Liver histology and function and protein nutrition were assessed in 9 male and 9 female patients undergoing small-bowel bypass for extreme obesity. Four months after surgery, when weight loss was rapid, SGOT was elevated in 12 patients, and most had marked hepatic steatosis. Of the essential amino acids, plasma valine, isoleucine, leucine, phenylalanine, threonine, and lysine declined, as did the nonessential amino acids alanine, citrulline, cystine, tyrosine, ornithine, and arginine. Glycine and serine were elevated. This profile is typical of protein-calorie malnutrition. Weight stabilization was achieved 12 to 36 months after surgery, at which time transaminase was normal and hepatic fat had diminished. The concentrations of many amino acids returned toward normal, although valine, isleucine, leucine, lysine, tyrosine, ornithine, and arginine remained depressed. Glycine remained elevated. The results of p.o. amino acid tolerance tests indicated that improved absorption accounted for the improved amino acid profiles. Thus, protein malnutrition contributes to hepatic dysfunction, and postoperative amino acid supplementation may be beneficial.

3302 STUDIES ON THE MODE OF ACTION OF CHOLERA TOXIN. EFFECTS ON SOLUBILIZED ADENYLATE CYCLASE. *(E.)* Beckman, B.; Flores, J.; Witkum, P. A.; Sharp, G. W. G. (Massachusetts Gen. Hosp., Boston). *J. Clin. Invest.* 53(4):1202-1205, 1974.

To gain further insight into the mechanism of action of cholera toxin, solubilized preparations of adenylate cyclase from control and toxin-treated livers of female Sprague-Dawley rats were studied. Adenylate cyclase activity was measured in both particulate and solubilized form in rat liver under control conditions and after i.v. injection of cholera toxin. Cholera toxin activated the adenylate cyclase in each animal with an average increase of 3.3-fold over controls in the particulate preparation and caused a 5.8-fold increase in the solubilized preparation. Thus, the ability of cholera toxin to stimulate adenylate cyclase is present even when the enzyme membrane environment is disrupted. Furthermore, the solubilized enzyme, after treatment with cholera toxin, retained its ability to respond to catecholamines, but not to glucagon. In contrast, the control enzyme lost its responsiveness to catecholamines and glucagon after solubilization.

3303 DIARRHEA TOXIN OBTAINED FROM A WATERBLOOM-PRODUCING SPECIES, MICROCYSTIS AERUGINOSA KUTZING. *(E.)* Aziz, K. M. S. (Inst. Public Health, Dacca, Bangladesh). *Science* 183(4130):1206-1207, 1974.

A diarrhea toxin obtained from *Microcystic aeruginosa* laboratory cultures has been isolated and assayed. Microcystis is widely distributed over the world and available to man and animals in many fresh water sources. Initial studies with centrifuged waterbloom consisting predominately of Microcystic aeruginosa obtained from a city pond demonstrated a lethal factor assayed by i.p. injections in rats. Subsequently, a Microcystis clone was established from a single cell cultured from a suspension of disrupted colonies separated by the extinction dilution method. The resulting preparation was assayed in ligated intestinal loops of guinea pigs. Two ml of the nondialyzable fraction of Microcystis toxin produced 0.33

ml of fluid/cm of small intestine of guinea pigs. When 3 ml of the dialyzable portion of the Microcystis whole cell lysate was injected in the loops, no fluid accumulation occurred. However, this dialyzable fraction killed rats when injected i.p. in 0.5 ml volumes. This data suggests a possible cause of diarrhea and diarrheal epidemics where no common source etiology is known and no person to person transmission can be established. It is noted that the use of surface water for drinking purposes where waterbloom is of common occurrence may be a health hazard.

3304 DESIGN AND EVALUATION BY NITROGEN BALANCE AND BLOOD AMINOGRAMS OF AN AMINO ACID MIXTURE FOR TOTAL PARENTERAL NUTRITION OF ADULTS WITH GASTROINTESTINAL DISEASE. *(E.)* Anderson, G. H.; Patel, D. G.; Jeejeebhoy, K. N. (Dept. Nutr., Univ. Toronto, Canada). *J. Clin. Invest.* 53(3):904-912, 1974.

An amino acid mixture was formulated for i.v. use containing 39.4% essential amino acids, with glycine, alanine, arginine, histidine, and proline selected to supply the nonessential nitrogen. Adult patients (2 males and 4 females, aged 24-66 yr) with gastrointestinal disease (including calcific pancreatitis (1), bleeding ulcer with dehiscence of wound and fistula (1), Zollinger-Ellison syndrome with fistula (1), short gut syndrome (1), Crohn's disease with enterocutaneous fistula (1), and post-gastrectomy malnutrition) were fed i.v. for 1 week at each of 3 levels of amino acid intake. All other nutrients were constant. Of these 6 patients, 4 were then fed 1.0 g/kg of egg or meat protein p.o. for 1 wk at the end of the 3 wk study while all other nutrients were fed i.v. Average nitrogen balances of 0.8, 0.5, and 2.2 g/day were observed when the amino acids infused were 0.25, 0.5, and 1.0 g/kg, resp. Fasting levels of threonine, glycine, cystine, methionine, isoleucine, tryptophan, and arginine, but not of the other amino acids, increased with the increment in input, although the levels were generally lower than normal. The increase in blood concentration during infusion was similar for each essential amino acid, indicating the supply of each amino acid was better balanced for utilization than casein hydrolysate. However, blood aminograms did suggest that some changes in composition of the mixture for the malnourished adult were desirable. The amino acid mixture used resembled that needed by the normal growing child. Nitrogen balance in the 4 orally fed patients showed that an amino acid mixture given i.v., provided it is well-balanced, can be utilized as efficiently as oral protein. It is concluded that the prediction of oral requirements for amino acids should be combined with observations on changes in blood aminograms during infusion over a range of amino acid input in the development of amino acid mixtures for i.v. feeding.

3305 COINCIDENT SALMONELLA INFECTIONS AND ULCERATIVE COLITIS: PROBLEMS OF RECOGNITION AND MANAGEMENT. *(E.)* Dronfield, M. W.; Fletcher, J.; Langman, M. J. S. (City Hosp., Nottingham, England). *Br. Med. J.* 1(5898):99-100, 1974.

Five cases of coincident salmonellosis and ulcerative colitis are described. In 3 the diagnostic combination was recognized late, but all cases had features that are difficult to reconcile with simple salmonella dystnery. In case 1 (a 55-yr-old man) the whole large bowel had typical features of ulcerative colitis with severe inflammation, psuedopolyp formation, ragged linear ulceration, and extensive mucosal stripping from the submucosa. Despite reversion to negative stool cultures, diarrhea worsened in case 2 (an 18-yr-old man) and the hemoglobin continued to fall. In case 3 (a 34-yr-old man) anemia was severe, and barium enema showed the typical pattern of chronic ulcerative colitis. A previous history of bloody diarrhea was obtained in case 4 (a 45-yr-old woman), and barium enema showed the characteristic changes of chronic proctosigmoid disease. In case 5 (a 20-yr-old man) the combination of chronic ulcerative colitis and salmonellosis was suggested by profuse bloody diarrhea for 2 weeks prior to admission, pronounced anemia, severe inflammatory change seen at sigmoidoscopy, and an abnormal result on barium enema. If corticosteroid therapy is given for the colitis once the combination is recognized, then simultaneous systemic antibiotic cover with ampicillin is advisable. Case 1 died during corticisteroid therapy alone (prednisolone 40 mg/day) with salmonella septicemia due to usually noninvasive *Salmonella typhimurium.*

GENERAL

Regional Enteritis

3365 RESULTS OF SURGERY FOR INFLAMMATORY BOWEL DISEASE: A FURTHER SURVEY OF ONE HOSPITAL REGION. *(E.)* Ritchie, J. K. (St. Mark's Hosp., London, England). *Br. Med. J.* 1(5902):264-268, 1974.

Case records have been studied for the results of surgery in 294 patients operated on for inflammatory bowel disease during 1967-72 at 34 nonteaching hospitals within the Northeast Metropolitan Hospital

Region. All patients treated surgically for acute colitis and those treated for chronic disease by total colectomy were included. The postoperative mortality of the primary surgery was 23.7%. The mortality was 2.1% in patients treated by elective operation, 37.6% in patients coming to urgent operation and 60.9% in patients treated by emergency operation. The three most important factors affecting the mortality were considered to be: increasing age of the patient, the presence of established colonic dilatation, and preoperative perforation of the colon.

3366 INTRAVENOUS HYPERALIMENTATION: IN THE TREATMENT OF INFLAMMATORY DISEASES OF THE BOWEL. *(E.)* Vogel, C. M.; Corwin, T. R.; Baue, A. E. (Jewish Hosp. St. Louis, Mo.). *Arch. Surg.* 108 (4):460-467, 1974.

Fifteen patients with regional enteritis (14) or ulcerative colitis (1): who were refractory to medical management were treated by bowel rest and i.v. hyperalimentation. Nine received i.v. hyperalimentation as primary therapy and all had remissions. Four have done well for 4 months to 3 yr. Four had recurrences and 1 died later. Six patients received i.v. hyperalimentation before planned operations for localized disease. Five had no recurrences for 6 months to 3 yr and 1 did not tolerate i.v. hyperalimentation. The role of i.v. hyperalimentation for inflammatory bowel disease can be both in preparation for operation and as primary therapy for acute episodes. I.v. hyperalimentation is reserved as primary therapy for patients with previous resections or extensive disease. It has provided prolonged remissions in some and prevented further operations in most. However, the long-term course of the disease was not altered.

3367 DIVERTING ILEOSTOMY FOR COLONIC CROHN'S DISEASE. PART I: SIGNIFICANCE OF ULCERS 5 MM IN DEPTH OR DEEPER ON THE PREOPERATIVE BARIUM ENEMA. *(E.)* Friedland, G. W.; Kohatsu, S.; Oberhelman, Jr., H. A. (Stanford Med. Ctr., Calif.). *Clin. Radiol.* 24(4):427-434, 1973.

In 21 patients with colonic Crohn's disease who had failed to respond to medical treatment, a diverting ileostomy resulted in persistent relief of symptoms in 60% of the cases. Preoperative radiographs for 10 patients (5 males and 5 females, aged 12-45 yr) who experienced persistent remission were reviewed together with radiographs for 5 patients (4 males and 1 female, aged 14-37 yr) in whom ileostomy had failed. Significantly, 80% of the failure patients' colons had raspberry thorn ulcers 5 mm or greater in depth compared with only 20% of the persistent remission group. Similarly, 80% of failure patients' colons had rose thorn or spike-like ulcers 5 mm or greater in depth compared with 30 and 40% resp., of the persistent remission group. Furthermore, 80% of colons in the failure group possessed all types of deep ulcerations, while only 30% of the persistent remission group were so affected. Ulcers 5 mm or greater in depth destroy the colonic muscularis propria and, if numerous, probably result in irreversible changes. If studies on larger numbers of patients confirm this finding, diverting ileostomy would be indicated before numerous deep ulcers develop. The following radiographic features did not appear to influence prognosis: haustral abnormalities, luminal abnormalities, colonic length and abscesses, distribution of the disease, nodules, and fistulas.

3368 DIVERTING ILEOSTOMY FOR COLONIC CROHN'S DISEASE. PART 2: RADIOLOGICAL FINDINGS IN THE COLON FOLLOWING DIVERSION. *(E.)* Friedland, G. W.; Kohatsu, S.; Oberhelman, Jr., H. A. (Stanford Med. Ctr., Calif.). *Clin. Radiol.* 24(4):435-439, 1973.

The radiological and clinical features preceeding and following diverting ileostomy for Crohn's disease were evaluated in 15 patients (9 males and 6 females, aged 12-58 yr). In the majority of patients who showed clinical improvement, ulcers and nodules gradually disappeared although their disappearance tended to lag behind clinical improvement. Radiological features which occurred only in patients showing clinical and radiological improvement were increases in length and width of the colon and reappearance of colonic haustra. Nonspecific radiological features which occurred both in patients who had an asymptomatic radiological relapse and in patients requiring colectomy for clinical and radiological relapse were severe narrowing and shortening of the colon, or reappearance of ulcers and nodules. Asymptomatic radiological relapse occurred in 7 cases. Such relapses generally consisted of reappearance or worsening of ulcers and nodules, and, in 1 patient, moderately severe narrowing of the lumen. Radiological follow-up is therefore essential. Intestinal continuity should not be reestablished if a radiological relapse is evident.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

'3 INFLUENCE OF ADRENALECTOMY AND β-METHASONE
ON THE COMPOSITION OF LIVER CELL MEMBRANE.
) Elert, O.; Staib, W. (Dept. Physiol. Chem.,
v. Dusseldorf, Germany). *Steroids Lipids Res.*
):65-75, 1973.

sma membranes were isolated from female Brünger
liver by centrifugation through a discontinuous
rose density gradient. The membranes were con-
inated by 6.7% microsomes and 3.3% mitochondria,
there was no DNA present. Examination under the
ctron microscope showed the preparation to be free
ribosomes, nuclei and bile canaliculi. The total
tein, cholesterol and carbohydrate composition
the membranes was measured, and the proteins
e further separated by acrylamide gel electrophor-
s. One week after adrenalectomy, the protein,
bohydrate and cholesterol contents of the liver
branes were significantly less than in membranes
m intact rats. Administration of β-methasone
1 or 4 hr caused the measured parameters to re-
n to values near to those found in intact animals.
may be assumed that 7 days after adrenalectomy,
influence on the intermediate metabolism has
en place and fewer plasma membranes are obtained.
t adrenalectomy a severe change in the interac-
n of protein and lipid layer of the membranes
occur with the result that the stabilizing effect
l be impaired, in particular if the membranes
ve their physiological surroundings. It is feas-
e that the binding capacity which stabilizes the
branes directly or indirectly has become affected
t adrenalectomy. To exclude a possible correla-
n between the effect of adrenal steroids on en-
e induction and the transport of amino acids,
ther studies on the effect of actinomycin D would
in the solution of this problem.

'4 ENDOCRINE CELLS IN THE HUMAN DUODENAL MU-
COSA: AN ULTRASTRUCTURAL STUDY. *(Fr.)*
xinos, J.; Balas, D.; Ribet, A. (Purpan Hosp.,
louse, France). *Biol. Gastroenterol. (Paris)*
):105-117, 1973.

er fixation with glutaraldehyde and osmium tetrox-
, electron microscope examinations were made of
duodenal specimens obtained by biopsy or at sur-
y from 6 subjects with no evidence of gastro-
estinal disease and 7 patients with ulcers, stom-
cancer, or chronic pancreatitis. At least 6
ferent types of endocrine cells were found.
se included L, S, I, D, EC (types 1 and 2), and
-like" cells. The endocrine cell density was high-
in the first and second third of the duodenum
decreased somewhat in the lower third. Although
re were large variations from one subject to
ther, endocrine cells accounted for about 5% of
cell population in the first two-thirds of the
denum and 1-2% in the lower third. The I cell,
ch is morphologically intermediate between L and
ells, probably does not represent a different
ge in maturation or secretion of the L and S cells
ce all 3 types were found in nonstimulated duo-
al mucosa.

3375 EFFECTS OF PROTEIN-CALORIE MALNUTRITION ON THE JEJUNAL MUCOSA OF TETRACYCLINE-TREATED PIGS. *(E.)* Neutra, M. R.; Maner, J. H.; Mayoral, L. G. (Harvard Med. Sch., Boston, Mass.). *Am. J. Clin. Nutr.* 27(2):287-295, 1974.

The effect of moderate protein-calorie depletion and subsequent repletion was studied in 40 pigs, and the morphological effects of simultaneously modifying the bacterial flora by chlortetracycline were determined when placed on a low protein diet (9.85 g/100 g of diet) for 14 weeks, all pigs had drastically reduced food intake and appeared stunted but not edematous. Pigs that continued on this diet for an additional six weeks remained anorexic and stunted, and 2 died. In contrast, pigs that were changed to a high protein diet (18.00 g/100 g of diet) at the end of the 14-week depletion period quickly increased their food consumption and grew rapidly; by the end of 20 weeks they had at least doubled their weight. In pigs on the low protein diet for 14 or 20 weeks, the jejunal mucosa were thin and both villi and crypts were shortened, although structurally normal. Pigs given the high protein diet for 6 weeks after the depletion period showed a highly significant increase in mucosal thickness, due to growth of both crypts and villi. Histologic comparison of jejunal mucosa from malnourished and repleted pigs revealed no consistent differences in villus width or in numbers of lymphocytes in the lamina propria. Connective tissue elements were proportionally reduced in the thin malnourished mucosas, and columnar absorptive cells were significantly shorter than in repleted pigs. Pigs which received chlortetracycline (0.03 g/100 g of food) tended to have slightly lower body weights and thinner jejunal mucosa than those not given antibiotic; this trend was present both in the malnourished and repleted dogs. The slight deleterious effect of chlortetracycline was probably due to direct inhibition of protein synthesis in epithelial cells, which in turn inhibited amino acid transport.

3376 COMPARATIVE STUDY OF BLOOD VESSELS IN THE HEPATIC PORTAL AND ITS VICINITY WITH SPECIAL CONSIDERATION OF THE GUINEA PIG. *(Ger.)* Von Haller, C.; Lade, R. (Animal Res. Lab., Univ. Frankfurt/Main, Germany). *Anat. Anz.* 135(1/2): 102-115, 1974.

ABSORPTION—EXCRETION—TRANSPORT

3391 QUANTITATIVE DIGESTION OF FRESH HERBAGE BY SHEEP. I. THE SITES OF DIGESTION OF ORGANIC MATTER, ENERGY, READILY FERMENTABLE CARBOHYDRATE, STRUCTURAL CARBOHYDRATE, AND LIPID. *(E.)* Ulyatt, M. J.; MacRae, J. C. (Applied Biochem. Div., Dept. Sci. Ind. Res., Palmerston North, New Zealand). *J. Agric. Sci. Camb.* 82(2):295-307, 1974.

Sheep prepared with a rumen cannula or a rumen cannula plus re-entrant cannulae in the duodenum and ileum were fed fresh 'Raunnui' perennial ryegrass (R), 'Manawa' short-rotation ryegrass (M), and white clover (C) at dry matter intakes ranging from 450 to 1000 g/24 hr. The re-entrant cannulated sheep were given paper impregnated with chromic oxide (Cr_2O_3) once daily *via* the rumen fistula as a marker; recoveries of Cr_2O_3 at the duodenum, ileum, and feces were approximately 75, 69, and 100%, resp. There were differences between pasture species in partition of organic matter (OM) and energy digestion. With M, digestion in the stomach was significantly less and digestion in the small intestine was significantly more than with either R or C. These partitions of OM and energy digestion changed with the level of feed intake. A substantial proportion of the digestible OM and energy was apparently digested in the large intestine with all three herbages. Approximately 93% of the digestible readily fermentable carbohydrate and 90% of the digestible structural carbohydrate was digested in the stomach region with all three herbages. Although the data do not provide an unequivocal explanation for the superiority of C over the ryegrasses in efficiency of utilization, it appears that differences between the egrasses in rate of breakdown in the rumen are ermined primarily by the rate at which the micro-ganisms can hydrolyse the plant structural carbo-drates.

92 INTESTINAL ABSORPTION OF D-XYLOSE AND FOLIC ACID IN PROTEIN-DEFICIENT PATAS

NKEYS (ERYTHROCEBUS PATAS). *(E.)* Gyr, K.; Wolf, H.; Felsenfeld, O. (Tulane Univ., Delta Primate Res. r., Covington, La.). *Am. J. Clin. Nutr.* :350-354, 1974.

testinal absorption of D-xylose and folic acid s studied before and during moderate protein de-ciency (serum albumin of 3 g/100 ml or less) by a rfusion technique in 8 patas monkeys (*Erythrocebus tas*). In 4 animals the study was repeated during covery from protein depletion. A mean of 15.8% ylose was absorbed during the base-line study mpared with 14.2% during protein depletion. Respec-ve values of folic acid absorption were 22.2 and .4%. The folic acid absorption returned to the se-line level during recovery. The drop in folic id absorption during protein deficiency was signi-cant. No corresponding histological changes of e intestinal mucosa were noted during the time of servation. The discrepancy between D-xylose and lic acid absorption may reflect different mechanisms absorption, folic acid depending much more on ac-ve transport. The process of active transport is st likely depressed by protein deficiency before ssive mechanisms, like diffusion, are affected.

93 THE EFFECTS OF INTESTINAL VASODILATOR MECHANISMS ON THE RATE OF ^{85}Kr ABSORPTION

THE CAT. *(E.)* Biber, B. (Dept. Physiol., Univ. teberg, Sweden). *Acta Physiol. Scand.* 90(3):578-2, 1974.

e absorption of ^{85}Kr from the small intestine of e cat was estimated during intestinal vasodilata-on induced by transmural electrical field stimula-on or by local intraarterial infusions (2.5-10.5 g/hr) of cholecystokinin or secretin. As blood ow increased, the rate of absorption was consider-ly augmented. Moreover, both electrical field imulation and hormonal infusion increased the rate ^{85}Kr absorption in excess of that seen during opropylnoradrenaline vasodilatation. An increased action of the intramural blood flow became fully uilibriated with luminal contents during the vaso-latory procedures, particularly during secretin ministration. The results suggest that a local crease and redistribution of blood flow, favoring e superficial mucosal layers, occurs postprandially the small intestine.

94 INHIBITORY EFFECT OF HIGH DIETARY ZINC ON COPPER ABSORPTION IN RATS.

(E.) Ogiso, ; Moriyama, K.; Sasaki, S.; Ishimura, Y.; Minato, (Fac. Pharm. Sci., Chiba Univ., Japan). *Chem. arm. Bull.* 22(1):55-60, 1974.

le Wistar rats fed a 1% zinc diet for 15 days owed significant decreases in body weight gain, ceruloplasmin activity, hemoglobin concentration, and copper content of liver, kidney, and serum. Zinc concentrations in liver, kidney, and serum increased markedly, suggesting that the decreases in copper content were a consequence of zinc accumulation. Copper uptake in liver of zinc-fed rats was reduced by administration of copper (4 mg/100 g), the reduction being higher for p.o. (82.7%) than for i.p. (42.3%) administration. Moreover, copper uptake in liver was depressed when copper and zinc were administered simultaneously to normal rats by the p.o. route. Short-term experiments with ^{64}Cu showed that zinc interferes with the absorption and utilization of copper: blood radioactivity of rats fed the 1% zinc diet for 9 days was much lower than in untreated controls. Biliary excretion of copper was less than 4.0 μg/100 ml in rats fed the high-zinc diet for 3 or 6 days, compared with 40.3 μg/100 ml in normal controls. These results indicate that disturbance of copper metabolism by zinc feeding is mainly due to the inhibition of copper absorption at the intestinal level.

3395 QUANTITATIVE DIGESTION OF FRESH HERBAGE BY SHEEP. II. THE SITES OF DIGESTION OF SOME NITROGENOUS CONSTITUENTS.

(E.) MacRae, J. C.; Ulyatt, M. J. (Applied Biochem. Div., D.S.I.R., Palmerston North, New Zealand). *J. Agric. Sci. Camb.* 82(2):309-319, 1974.

Sheep prepared with a rumen cannula or a rumen cannula plus re-entrant cannulae in the duodenum and ileum were fed fresh "Raunnui" perennial ryegrass (R), "Manawa" short-rotation ryegrass (M), and white clover (C) at dry matter intakes ranging from 450-1000 g/24 hr. At an intake of 500 g, the amounts of nonammonia-nitrogen (NAN) entering the small intestine were significantly greater in sheep given M than in sheep given R or C. At an intake of 800 g, the amounts in sheep given M were significantly greater than in sheep given R. NAN leaving the small intestine and nitrogen excreted in the feces were similar for all three diets. At an intake of 800 g, the apparent absorption of NAN from the small intestine of sheep given M and C was significantly greater than that of the sheep given R. As the intake of herbage was increased, the partition of digestion altered. Only small differences between herbages were found in the amino acid composition of the duodenal and ileal digesta, but because of the large differences in the flow of NAN, the apparent absorption of individual amino acids from the small intestine was much higher in sheep given M than in sheep given R or C.

3396 QUANTITATIVE DIGESTION OF FRESH HERBAGE BY SHEEP. III. THE MOVEMENT OF Mg, Ca, P, K AND Na IN THE DIGESTIVE TRACT.

(E.) Grace, N. D.; Ulyatt, M. J.; MacRae, J. C. (Applied Biochem. Div., D.S.I.R., Palmerston North, New Zealand). *J. Agric. Sci. Camb.* 82(2):321-330, 1974.

Sheep prepared with a rumen cannula or a rumen cannula plus re-entrant cannulae in the duodenum and ileum were fed fresh 'Ruannui' perennial ryegrass (R), 'Manawa' short-rotation ryegrass (M), and white clover (C) at dry matter intakes ranging from 450-1000 g/24 hr. Paper impregnated with chromic oxide was given once daily *via* the rumen fistula as a marker. The quantities of Mg (at high intake), Ca, and K (except in sheep fed M) leaving the stomach were significantly lower than the amounts consumed, while the amounts of P and Na leaving the stomach were significantly higher. The quantities of Mg (at high intakes) and Ca leaving the small intestine were significantly higher than the corresponding quantities entering the small intestine, while the amounts of P, K, and Na leaving the small intestine (at high intakes) were significantly lower. The amounts of Na (at high and low intakes) and the other mineral elements (at high intakes) excreted in the feces were significantly less than the amounts entering the large intestine. Thus, at higher intakes there were net absorptions of Mg, Ca, and K (except in sheep fed M) from, and net secretions of P and Na into, the stomach. The small intestine was the major site of net absorption for P and K and a minor site for Na, while a net secretion of Mg and Ca occurred into this region. The net absorption of Mg, Ca, P, K, and Na occurred from the large intestine at the higher intakes.

3397 THE INTESTINAL ABSORPTION OF DYPHENYLHYDANTOIN FROM A SUSPENSION IN RATS. *(E.)*

Van Rees, H.; Noach, E. L. (Dept. Pharmacol., Univ. Leiden, Netherlands). *Arch. Int. Pharmacodyn. Ther.* 206(1):76-83, 1973.

The duodenum, jejunum plus ileum, or colon was isolated in male albino rats using ligatures on both ends. Diphenylhydantoin (DPH, 3 or 6 mg) was then administered intraluminally into the isolated gut sections as a suspension in a 10% gum arabic solution. The DPH content of the small intestine decreased linearly with time during the first 6 hr after administration, after which the rate of decrease diminished. The results were independent of dose and site of administration. The decrease in the DPH content of the colon was nonlinear. The decrease in the total gut content of DPH appeared to be a first order process. The results indicated that the rate-limiting factor in the intestinal absorption of DPH was the dissolution process from the suspension.

3398 INTESTINAL TRANSPORT OF CARBOHYDRATES AS MEASURED BY PORTAL CATHETERIZATION IN MAN. *(E.)*

Dencker, H.; Meeuwisse, G.; Norryd, C.; Olin, T.; Tranberg, K.-G. (Dept. Surg., Pediatrics, Roentgen Diagnostics, Univ. Lund, Sweden). *Digestion* 9(6):514-524, 1973.

A method for studying the transport of an intraduodenally instilled solution of carbohydrates by simultaneous sampling of portal and arterial blood is described. The transport of glucose, maltose and fructose was measured in ambulant adult patients with cancer of the colon without liver metastases. They were in a normal nutritional state; 200 ml of a 6% carbohydrate solution was instilled intraduodenally within 10 minutes. Portal glucose rise was not slower after instillation of maltose than after that of glucose. Transport of fructose was completed somewhat later than that of glucose. The difference in the portal-arterial blood sugar concentration was used as a measure of the actual net influx of carbohydrates into the portal circulation at certain intervals. After instillation of glucose or maltose the portal-arterial glucose difference showed 2 maxima. The interposed minimum often reached a slightly negative value. It is tentatively assumed that this unexpected finding was due to accumulation of glucose in the intestinal mucosa, followed by a release of the accumulated glucose coinciding with the subsequent fall of arterial blood glucose concentration. Absorbed fructose did not behave in the same manner. Although some transformation of fructose to glucose during transport through the intestinal wall may have occurred, it was less than could be detected in these experiments.

3399 THE FATTY ACID COMPOSITION OF THE MAIN PHOSPHOLIPID FRACTIONS OF THE RUMEN AND ABOMASUM TISSUES OF FOETAL AND ADULT SHEEP. *(E.)*

Body, D. R.; Shorland, F. B. (Applied Biochem. Div., D.S.I.R., Palmerston N., New Zealand). *J. Sci. Food Agric.* 25(2):197-204, 1974.

The fatty acid composition of the phosphatidyl choline, phosphatidyl ethanolamine, and sphingomyelin fractions of the rumen and abomasum tissues of fetal and adult Romney sheep was determined. The major proportion of the polyunsaturated fatty acids was in the phosphatidyl ethanolamine fraction, being reduced in the other two fractions. The phosphatidyl ethanolamine fractions were further characterized by a comparatively low palmitic acid content and the presence of cyclopropane fatty acids. The sphingomylein fractions contained relatively large amounts of higher n-saturated fatty acids, the total amounts of acids above C_{20} tending to vary inversely with the levels of palmitic acid; the levels of stearic acid remained relatively constant. Although the fatty acid composition did vary markedly with age, the fetal tissues, in contrast to the adult tissues, contained substantial amounts of eicos 5,8,11-trienoic acid and relatively small amounts of linolenic and linoleic acids and acids of the $\omega 3$ series. The results are consistent with a requirement for C_{20} and C_{22} polyunsaturated acids of the $\omega 3$ and $\omega 9$ series and some penetration of maternal fatty acids through the placenta. The resemblance between the fatty acid make-up and the composition of the fetal and maternal phospholipids suggests the possibility of transference of intact or lysophospholipids from the mother to the fetus via the placenta.

3400 INTESTINAL ABSORPTION OF VITAMIN B_6. I. PYRIDOXOL UPTAKE BY RAT INTESTINAL TISSUE. *(E.)*

Tsuji, T.; Yamada, R.; Nose, Y. (Kyoto Prefectural Univ. Med., Kyoto, Japan). *J. Nutr. Sci. Vitaminol.* 19(5):401-417, 1973.

Small ring segments from the small intestine of male Wistar rats were incubated with ^{3}H-pyridoxal. Subsequent accumulation studies indicated that the content of compounds increased in intestinal

ssue when it was incubated with dilute solutions of
ridoxol. This accumulation occured primarily *via*
e metabolic conversion of pyridoxol to B_6 phospates.
e mechanism of pyridoxol uptake consisted of two
eps: entrance into the tissue, and metabolic
nversion in the intracellular space. Pyridoxol
parently enters the intracellular fluid space by
mple diffusion, although there is a less likely
ssibility that 2 distinct mechanisms are involved
the uptake process.

01 INOSITOL DEFICIENCY IN GERBILS: DIETARY
EFFECTS ON THE INTESTINAL LIPODYSTROPHY.
) Kroes, J. F.; Hegsted, D. M.; Hayes, K. C.
rvard Sch. Public Health, Boston, Mass.). *J.*
r. 103(10):1448-1453, 1973.

e effects of coconut oil, partially purified tri-
cerides, and dietary cholesterol on the induction
the intestinal lipodystrophy were investigated in
ale gerbils fed diets low in inositol. When the
ositol-deficient diet was fed with saturated tri-
cerides, maximal gut lipid was found with trigly-
rides rich in lauric acid (12:0) and somewhat less
th those rich in capric acid (10:0) and myristic
id (14:0), these being the major fatty acids in
conut oil. Increasing chain length decreased the
cumulation of gut lipid. No excess was found with
iglycerides rich in caprylic acid (8:0), presum-
ly absorbed through the portal system, or with
earic acid (18:0). The latter, however, was poorly
sorbed. Unsaturated triglycerides rich in oleic
linoleic acids (18:1 ω 9 and 18:2 ω 6) also pro-
ced no accumulation of gut lipid. Feeding 0.2 to
5% of cholesterol accentuated the lipodystrophy,
t this was prevented by inositol. The resistance
male gerbils to the lipodystrophy was eliminated
castration, indicating that testicular synthesis
inositol was a major factor in the difference be-
een male and female gerbils. It appears that the
eding of large amounts of certain fats to gerbils
creases the inositol requirement for the formation
lipoproteins or their transport from the mucosal
lls. This implies that the gerbil either has a
ique inositol-dependent mechanism for the synthe-
s and transport of intestinal lipoproteins, or that
is species differs in its ability to synthesize
fficient endogenous inositol. The latter seems
re probable. Inositol had an effect on the circu-
ting cholesterol concentration that was affected
the type of dietary fat and sex of the gerbil.
e basic response to saturated fat in both males and
males is an elevation in the plasma cholesterol.
en dietary inositol is limiting, the male presum-
ly maintains this rise with endogenous synthesis
the testes, whereas the female cannot meet the
dogenous requirement and her plasma cholesterol
clines as the lipodystrophy develops. It is
ncluded that only in the presence of an adequate
pply of inositol was the effect of dietary fat and
olesterol on circulating cholesterol clearly
own.

02 INCREASE OF ACTIVE TRANSPORT OF CONJUGATED
BILE SALTS IN STREPTOZOTOCIN-DIABETIC RAT
ALL INTESTINE. *(E.)* Caspary, W. F. (Univ. of
ttingen, Germany). *Gut* 14(12):949-955, 1973.

Active transport of conjugated bile salts, Na-tauro- and Na-glycocholate and D-galactose, was examined in the small intestine of streptozotocin-diabetic female Wistar rats by an *in vitro* technique. Tissue uptake and mucosal to serosal transport of conjugated bile salts and D-galactose was enhanced in diabetic rat ileum. The minimal transport capacity for conjugated bile salts in the jejunum did not differ between diabetic and control intestine. D-galactose transport and transport of 3-0-methyl-glucose were, however, enhanced in diabetic jejunum as well. Kinetic analysis of the initial uptake rates for conjugated bile salts revealed that the maximal transport capacity (Vmax) was enhanced in diabetic ileum. In accordance with earlier results on the effect of experimental diabetes mellitus on digestive-absorptive functions it is suggested that experimental diabetes mellitus increases the transport capacity of active, Na^+-dependent intestinal transport processes in general. It is concluded that experiments *in vivo* will be necessary to show whether the observed increase of ileal bile salt reabsorption in experimental diabetes mellitus will have an effect on bile salt pool size or synthesis rate. Under conditions of increased reabsorptive capacity for bile salts in diabetic small intestine, bile salt synthesis by the liver might be expected to be decreased. Although no data are available on bile acid synthesis rates in streptozotocin-diabetes, the increased transport capacity for conjugated bile salts could be an adaptive process of the ileum due to an increased bile acid synthesis rate in the liver. Consequently, the transport capacity for bile salts increases as a result of increased bile salt pool size.

3403 DIMENSIONS OF POLAR PATHWAYS THROUGH RABBIT GALLBLADDER EPITHELIUM. THE EFFECT OF PHLORETIN ON NONELECTROLYTE PERMEABILITY. *(E.)* Van Os, C. H.; De Jong, M. D.; Slegers, J. F. G. (Dept. Physiol., Univ. Nijmegen, Netherlands). *J. Membrane Biol.* 15(4):363-382, 1974.

MOTILITY

3414 A DEMONSTRATION OF VAGAL ADRENERGIC VASCULAR AND MOTOR INFLUENCES IN THE SMALL INTESTINE OF THE DOG. *(E.)* Martin, J. S.; Innes, D. L.; Tansy, M. F. (Temple Univ. Sch. Dentistry, Philadelphia, Pa.). *Surg. Gynecol. Obstet.* 138(1): 6-12, 1974.

Experiments with anesthetized dogs indicate that electric stimulation of the peripheral vagi can elicit both adrenergic and cholinergic vascular and intestinal motor events. In dogs which underwent bilateral vagectomy, peripheral vagal stimulation at the cervical level with stimuli of low voltage and frequency produced the classical cholinergic cardiovascular response. Application of the same stimulus to the distal end of the dorsal or ventral abdominal portion of the vagus, however, increased both femoral and mesenteric arterial pressure. In the majority of dogs, the systemic pressor effect was produced by peripheral stimulation of the dorsal portion of the vagus whereas a depressor effect was usually obtained by stimulation of the ventral trunk. The pressor response was blocked by the alpha adrenolytic, phenoxybenzamine. Supradiaphragmatic vagal stimulation also resulted in an observable reduction of jejunal motor activity. In view of the neurophysiologic and histochemical evidence advanced by other workers, these observations suggest that some vagal nerve fibers may exert a functional adrenergic influence upon the intestine and its circulation.

3415 AUGMENTATION OF THE NEURAL INHIBITORY RESPONSE OF THE LOWER ESOPHAGEAL SPHINCTER. *(E.)* Cohen, S. (Univ. Pennsylvania Hosp., Philadelphia). *Proc. Soc. Exp. Biol. Med.* 145(3):1004-1007, 1974.

The effect of lidoflazine and dipyridamole upon the nonadrenergic inhibitory response of the lower esophageal sphincter circular muscle was studied *in vitro*. Both dipyridamole and lidoflazine significantly potentiated the maximal inhibitory responses of the lower esophageal sphincter muscle to electrical stimulation during muscle contraction produced by either acetylcholine or KCl depolarization. Theophylline did not alter the magnitude of the inhibitory response. These studies indicate: 1) lower esophageal sphincter muscle neural inhibition may be potentiated by compounds known to block the intracellular uptake of adenosine, and 2) nonadrenergic inhibition of lower esophageal sphincter muscle may be mediated through adenosine triphosphate or a related purine nucleotide as proposed for other muscles responding similarly to dipyridamole and lidoflazine.

3416 A NERVOUS MECHANISM FOR DESCENDING INHIBITION IN GUINEA-PIG SMALL INTESTINE. *(E.)* Hirst, G. D. S.; McKirdy, H. C. (Dept. Physiol., Monash Univ., Clayton, Victoria, Australia). *J. Physiol. (Lond.)* 238(1):129-143, 1974.

Intracellular recordings were made from neurones in the myenteric plexus of guinea-pig small intestine under conditions in which these neurones received synaptic input from an adjacent segment of intestine. Most long synaptic pathways in the myenteric plexus

d in an anal direction. Such pathways could be
ited by either distension or transmural electri-
stimulation of the intestinal segment. Similar
muli evoked inhibitory junction potentials in the
cular muscle layer but only on the anal side of
stimulated region of intestine. The main fea-
es of the proposed inhibitory pathway include:
the afferent processes of the sensory neurone
stimulated by distension; 2) the efferent pro-
sses impinge on the cell body of an interneurone
may impinge directly on the cell body of an in-
itory neurone; 3) inhibitory fibers run in an anal
ection; and 4) inhibitory transmitter is assumed
be released from varicosities.

17 AN EVALUATION OF NEURAL INFLUENCES ON THE SPHINCTER OF ODDI IN THE DOG.

(E.) Tansy,
F.; Innes, D. L.; Martin, J. S.; Kendall, F. M.
ept. Physiol., Temple Univ., Philadelphia, Pa.).
J. Dig. Dis. 19(5):423-437, 1974.

ening pressures of the choledochoduodenal junction
re measured in anesthetized dogs before and after
gotomy. Measurements were also made in anesthe-
zed, vagotomized dogs prior to and during appro-
iate electrical stimulation of the severed ends
the peripheral and central vagi and of the peri-
eral splanchnic nerves. Vagotomy itself was not
sociated with significant changes in mean ductal
ening pressures. Central and peripheral vagal
imulation and peripheral splanchnic nerve stimu-
tion did not significantly change the mean opening
essure, but changes in circulating fluid volume
d have a significant effect. Reductions in sys-
mic arterial pressure were associated with a re-
ction in mean opening pressures, whereas increases
cardiovascular fluid volume were associated with
marked elevation of opening pressures. It is con-
uded that ductal opening pressures can be signi-
cantly changed by hydraulic factors but are ap-
rently unresponsive to direct nervous control.

18 GASTRIC EMPTYING AND SMALL INTESTINAL PROPULSION IN MICE FOLLOWING IRRADIATION OF
E ABDOMEN.

(E.) Frankendal, B. (Dept. Gynecologic
diation Therap., Umea Univ., Sweden). *Acta Radiol.*
her.) 12(6):529-540, 1973.

test meal containing a radioactive isotope
a$_2$^{51}CrO$_4$) was deposited in the stomach and its
istribution in the alimentary tract measured post
rtem in female NMRI mice treated by different ir-
diation schedules. Irradiation with 250 rad daily
to a total dose of 4,000 rad had no demonstrable
fect on gastric emptying. A daily dose of 500 rad
to a total dose of 1,000 and 2,000 rad inhibited
astric emptying and accelerated propulsion of the
ntents of the small intestine.

3419 SOME ACTIONS OF SYMPATHOMIMETIC AMINES AND THEIR ANTAGONISTS ON MOUSE SUPERFUSED ILEUM.

(E.) Large, B. J.; Wright, J. L. (Sch. Med., Leeds, England). *Br. J. Pharmacol.* 49(4):702-705, 1973.

Superfused segments of ileum from Tuck No. 1 mice exhibited spontaneous movements which were inhibited by sympathomimetic amines. Isoprenaline and epinephrine were about equipotent: 2-5 ng produced a 50% maximal response. Norepinephrine and phenylephrine were each about 1/15 as potent as the former drugs. Supersensitivity developed to all these agents when mice were "sympathectomized" with nerve growth factor antiserum (0.05 ml s.c. for 5 consecutive days) or 6-hydroxydopamine (2 separate injections of 50 mg/kg i.v., followed by a single injection of 100 mg/kg). The supersensitivity was more pronounced with the latter treatment. Responses to the amines were reduced by phentolamine mesylate (1 μg/ml) and propranolol hydrochloride (0.5 μg/ml), alone or in combination. Phenylephrine simply shortened the responses after β-adrenoceptor blockade. No qualitative changes were evident in the effects of the blocking agents after "sympathectomy."

3420 EFFECT OF L-DOPA ON DUODENAL MOTILITY IN THE DOG.

(Fr.) Patay, M.; van de Driessche, J.; Le Clec'h, G. (Univ. Hosp. Ctr., Rennes, France). *C. R. Soc. Biol. (Paris)* 167(8/9):1262-1265, 1973.

Pressure was measured in the duodenum of 25 chloralose-anesthetized mongrel dogs before and after slow (5 min) i.v. injection of 40 mg/kg L-dopa alone or after pericyazine (3 mg/kg), propranolol (600 μg/kg), or seryl trihydroxybenzyl hydrazine (40 mg/kg); epinephrine (7 μg/kg); phenylephrine (100 μg/kg); isopropyl norepinephrine (10 μg/kg); tyramine (250 μg/kg); and dopamine (40 μg/kg). After a short latent period, L-dopa caused significant inhibition of motility for 54 min or more. This inhibition affected the amplitude more than the frequency. Injection of sympathomimetic agents epinephrine, phenylephrine, isopropyl norepinephrine, tyramine, and dopamine) caused immediate but short-term (2-4 min) inhibition. In contrast to the action of α- or β-adrenergic blocking agents when they were administered simultaneously with L-dopa, injection of pericyazine and propranolol, resp., after L-dopa had no effect on the inhibitory action of L-dopa. It is suggested that L-dopa acts on both α- and β-adrenergic receptors.

3421 SYMPATHETIC INNERVATION OF THE GASTROINTESTINAL TRACT OF MAMMALS.

(E.) Krokhina, E. M. (Inst. Normal Path. Physiol., Acad. Med. Sci., USSR). *Arch. Anat. Microsc. Morphol. Exp.* 62(3):307-321, 1973.

The sympathetic components of the vegetative innervation of frozen, air-dried sections of the walls of the feline esophagus, stomach, duodenum, and ileum were examined using fluorescence microscopy. Varicose adrenergic fibers were detected in the intermuscular nerve plexus. The nerve ganglia of Auerbach's plexus contain 3 colonies of neurones, which have been found in the walls of the pyloric portion of the stomach and duodenum. The extrinsic muscular coat and the tunica muscularis mucosae of the gastrointestinal tract receive their adrenergic innervation from three sources: adrenergic fibers emerging from vascular and perivascular adrenergic plexuses in the intestinal wall; adrenergic fibers emerging from Auerbach's plexus; and adrenergic intramural neurons. The highest density of adrenergic terminals per unit of innervated area is in the circular layer of smooth muscle in the subdiaphragmatic section of the esophagus, the pyloric sphincter, and the walls of the duodenum and jejunum. Within the longitudinal muscles there is a well-developed adrenergic network which is partially adjacent to Auerbach's plexus. Adrenergic fibers often innervate other tissues in the gastrointestinal wall, such as loose connective tissue, glandular tissue, and the lymphatic nodes; these tissues often contain vascular adrenergic plexuses.

3422 THE SYMPATHETIC INNERVATION OF THE RAT GASTRIC FUNDUS. *(E.)* Heazell, M. A. (Dept. Pharmacol., King's Coll., London, England). *Arch. Int. Pharmacodyn. Ther.* 206(2):253-263, 1973.

A rat celiac artery-fundus preparation is described in which the activity of the fundal smooth muscle can be recorded *in vitro* during the electrical stimulation of the perivascular nerves of splanchnic origin. When the isolated celiac artery-fundus preparation was stimulated periarterially with relatively narrow pulses, a rapidly developing relaxation was observed. This response was reduced and eventually abolished by bethanidine, the blocking action of which was slightly reversed by dextroamphetamine and ephedrine but prevented or reduced in preparations which had been pretreated with either of these sympathomimetic amines. There was no response to periarterial stimulation of a celiac artery-fundus preparation from a rat which had received reserpine in a dose which caused noradrenaline depletion. When this reserpinized tissue was prepared as a strip and stimulated transmurally, there was a slowly developing process of relaxation. It is concluded that the rat gastric fundus receives a periarterial inhibitory innervation from the celiac ganglion and that these fibers are adrenergic. There is also an inhibitory response to the transmural stimulation of reserpinized tissues which involves nonadrenergic nerves.

3423 EFFECTS OF DIETARY SUPPLEMENTS OF WHEAT BRAN AND CELLULOSE ON FAECES AND BOWEL FUNCTION. *(E.)* Eastwood, M. A.; Kirkpatrick, J. R.; Mitchell, W. D.; Bone, A.; Hamilton, T. (Western Gen. Hosp., Edinburgh, Scotland). *Br. Med. J.* 4(5889):392-394, 1973.

In a study of bowel function in 8 healthy males (aged 25-43 yr) wheat bran or cellulose (16 g/day) was added to the diet for 4 weeks. Wet and dry stool weight increased significantly after ingestion of bran. The most striking increase was in the wet weight (107 to 174 g/day); the average daily increase in dry weight was equivalent to the amount of bran ingested. Intestinal transit time did not alter significantly. Fecal bile acids did not increase but were diluted (wet feces from 2.06 to 1.08 mg/g; dry feces from 8.1 to 1.9 mg/g). Serum cholesterol levels did not change. The effects of cellulose, tested on 4 of the 8 subjects, were similar to those of bran. The possible therapeutic effect of bran or cellulose in diverticular disease is apparently due to the ability of these substances to increase stool bulk.

SECRETION AND METABOLISM

34 THE EFFECT OF PROSTOGLANDIN E_1 ON THE RELEASE OF GASTRIN AND GASTRIC SECRETION ON GS. *(E.)* Becker, H. D.; Reeder, D. D.; Thompson, . C. (Dept. Surg., Univ. Texas Med. Br., Galveston). *ndocrinology* 93(5):1148-1151, 1973.

ne effect of prostaglandin E_1 (PGE_1) on the basal nd food-stimulated concentrations of serum gastrin as studied in 5 adult mongrel dogs with denervated undic (Heindenhain) pouches. The PGE_1 infusion aused an 80% inhibition in the secretory response f the denervated fundic pouch to food, but it did ot alter the basal serum gastrin levels. After the nfusion was stopped, the gastric secretion rose to reater than control levels in the food-stimulated nimals. Because of this rebound effect, the total -hr Heidenhain pouch acid output in response to ood was unchanged. The results indicate that PGE_1 as a direct inhibitory effect on the parietal cells. he mechanism by which PGE_1 increases food-stimulated astrin levels may involve a diminished acid inhibiion of the antrum, a decreased antral motility, or n alteration in the catabolic pathways.

SECRETION AND METABOLISM

Stomach

438 THE VALUE OF A COOPERATIVE MULTICENTER STUDY FOR ESTABLISHING A TABLE OF NORMAL ALUES FOR GASTRIC ACID SECRETION AS A FUNCTION OF EX, AGE, AND WEIGHT. *(Fr.)* Bernier, J. J.; Vidon, .; Mignon, M. (St. Lazare Hosp., Paris, France). *iol. Gastroenterol. (Paris)* 6(4):287-296, 1973.

asal acid outputs and peak acid outputs after administration of histamine dihydrochloride (0.01 mg/kg ollowed, 1 hr later, by another injection of the ame dose), pentagastrin (3-6 μg/kg/hr), and swine astrin (2-5 μg/kg/hr) were measured in 53 subjects (38 men and 15 women) with no radiological or histological evidence of stomach disease. Values for the exchangeable potassium (K) pool were calculated from the subjects' age and weight. Acid output values were correlated with values for the exchangeable K pool rather than with the lean body mass since the latter includes extracellular liquid and the skeleton in addition to cells. The acid output correlated with the exchangeable K pool did not differ in either sex with the stimulant used, but the true acid output was about 30% higher in men than in women. Analysis of variations in the exchangeable K pool with age showed that the former decreased about 0.4%/yr at ages above 14 yr. Literature reports indicate that gastric acid secretion declines more sharply than this value above age 50 yr, but this could be explained by failure to exclude subjects who have gastritis or by the use of populations with lower body weights than those of Europeans. Tables are presented showing the exchangeable K pool as a function of sex, age, and weight. These tables should be used cautiously since larger numbers of subjects must be studied to verify the values.

3439 EFFECT OF TRITERPENOIDS RELATED TO CARBENOXOLONE UPON HUMAN PEPSINS AND PEPSINOGENS AND UPON BOVINE TRYPSIN AND CHYMOTRYPSIN. *(E.)* Waft, L. A.; Roberts, N. B.; Taylor, W. H. (United Liverpool Hosp., England). *Clin. Sci. Mol. Med.* 46(4):519-526, 1974.

Sixteen triterpenoid compounds related to glycyrrhetic acid were tested for anti-pepsin, anti-pepsinogen, anti-trypsin, and anti-chymotrypsin activity. Their actions were compared with the known inhibitory actions of carbenoxalone, which is clinically effective in the healing of chronic gastric ulceration in man. 3-*O*-lauroyl-11-oxo-18α-olean-12-en-30-oic acid, known to be clinically ineffective in the healing of gastric ulceration, was without significant inhibitory effect on any of the enzymes tested. Good anti-pepsin activity was associated with cleaving the A ring with retention of a C-3 carboxyl group and a free C-30 carboxyl group. Good anti-pepsinogen activity was associated with removing the C-11 oxo group and/or switching the carboxyl group from C-30 to C-28. These results provide a guide for the synthesis of new anti-pepsin and potential anti-ulcer triterpenoid derivatives. Homologous enzymes, human pepsin 3 and swine pepsin A, were affected by each of the 16 compounds to a remarkably similar degree. The correlation between effects of the compounds on pairs of enzymes may thus be used as a measure of the structural similarity of the enzymes. The correlation coefficients are high among individual pepsins and individual pepsinogens. Triterpenoids with high anti-trypsin and anti-chymotrypsin activity had little in common other than a substituted cyclic group. The compounds which inhibit trypsin and chymotrypsin may be of use in diseases in which pancreatic enzymes are released (e.g., acute pancreatitis and pancreatic fistulas).

3440 RADIOIMMUNOASSAY OF GASTRIN. FASTING SERUM LEVELS IN HUMANS WITH NORMAL AND HIGH GASTRIC ACID SECRETION. *(E.)*

Gedde-Dahl, D. (Univ. Hosp., Rikshospitalet, Oslo, Norway). *Scand. J. Gastroenterol.* 9(1):41-47, 1974.

A radioimmunoassay for gastrin giving accuracy, sensitivity and precision parameters, using rabbit anti-albumin-SHG as antiserum and Dextran-coated charcoal for separation is described. In 298 patients with different diseases but with normal or high pentagastrin-stimulated gastric acid secretion, fasting serum gastrin concentrations were determined. A mean of 65.9 pg/ml and a normal range of 10 to 150 pg/ml were found in the 205 patients with normal gastric acid secretion. No differences were found between sexes or age groups, nor was any difference found between patients with normal and high gastric acid secretion. No correlation was found between basal acid output or maximal acid output and fasting serum gastrin concentration in these patients. Persons with ulcus corporis ventriculi had significantly higher fasting serum gastrin levels than others whereas peptic ulcer patients did not differ from normals.

3441 GASTRIC STIMULATION BY INTRAVENOUS INJECTION OF CHOLECYSTOKININ AND SECRETIN IN FISTULA CHICKENS. *(E.)*

Burhol, P. G. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(1):49-53, 1974.

The effect of i.v. injection of cholecystokinin and secretin on gastric secretion was studied in 10 fistula chickens. Cholecystokinin elicited a significant, dose-dependent and fivefold rise in the gastric H^+ secretion, whereas the pepsin secretion showed a slight and not significant rise. It is suggested that cholecystokinin compared with pentagastrin may be a full agonist for stimulation of gastric H^+ and a partial agonist for stimulation of pepsin secretion in the chicken. Secretin caused a significant, dose-dependent and some threefold increase both in the gastric H^+ and the pepsin secretion. It is proposed that secretin stimulates the gastric secretion in the chicken by a direct action on the gastric mucosa. It is concluded that the gastric stimulation by the intestinal hormones cholecystokinin and secretin in this study, may be taken to support the hypothesis that the intestinal phase seems to be more important in the physiological stimulation of gastric secretion in birds than in mammals.

3442 EFFECTS OF ELEMENTAL DIETS ON GASTRIC EMPTYING AND GASTRIC SECRETION IN MAN. *(E.)*

Bury, K. D.; Jambunathan, G. (Dept. Surg., Univ. Toronto, Canada). *Am. J. Surg.* 127(1):59-64, 1974.

The patterns of gastric emptying and acid secretion were documented and compared after rapid ingestion of 2 different volumes of 4 test meals. The test meals included: (1) water; (2) blenderized food with osmolality 1027, chloride 21.9, fat 6.7, protein 16, and carbohydrate 121 g/100 ml; (3) Vivonex (Orange) with osmolality 1247, chloride 69.1, fat 0.413, protein 11.438, and carbohydrate 127.12 g/100 ml; and (4) Flexical (Orange) with osmolality 1158, chloride 56.4, fat 22.28, protein 14.1, and carbohydrate 103.73 g/100 ml. The Flexical diet contained fat as a combination of whole fat and middle chain triglycerides. The blenderized diet consisted of eggs, bread, orange juice, apple sauce, lipomul, and added sugar. The half-life of the 300 ml elemental diets was significantly longer than that of the blenderized food, and total emptying time was prolonged to 118 and 141% of the control diet with Flexical and Vivonex, respectively. All 600 ml test meals, except water, caused an initial increase in gastric volume and total emptying time was prolonged. The 300 ml blenderized test diet stimulated significantly greater acid output from the stomach in the first hour after ingestion. Except for 600 ml of Flexical, all 600 ml diets stimulated significantly higher acid outputs than did 300 ml of the same test meal. Total acid secretion was greatest in response to blenderized test meals. All test diets (except water) were significantly hyperosmotic, with similar pH values. After all test meals (except water) osmolality of gastric contents progressively decreased towards isotonicity. The osmolality of the gastric contents increased with time after water ingestion. It is concluded that elemental diets should be ingested as frequent small feedings or continuous feedings.

3443 EFFECTS OF ACID IN STOMACH AND DUODENUM UPON THE GASTRIC MYOELECTRICAL ACTIVITY IN MAN. *(E.)*

Couturier, D.; Roze, C.; Vasconcellos, D.; Accary, J. P.; Debray, C. (Bichat Hosp., Paris, France). *Digestion* 9(6):502-513, 1973.

The period of the pacesetter potentials in the normal human stomach was studied when infusing HCl (75 mEq/l) or saline in the stomach or duodenum. When

350 ml volume of saline was infused into the stom- n, an 11% increase of the pacesetter potentials riod was observed. With 350 ml of acid solution, e maximum increase was 40%. This occurred 8 min ter the onset of infusion, at the moment when the rum gastrin level was significantly lowered. When e acid solution was infused into the duodenum, a ow rate of acid dependent increase of the paceset- r potentials period occurred (43% with 4 ml/min). line induced no change. A single i.v. injection secretin (0.5 U/kg) induced an increase in the cesetter potentials period whose maximum (35%) curred 4 min after the injection. The results ggest that gastric myoelectrical activity may be fected by a hormonal regulation in which endogenous cretin and gastrin would determine opposite res- nses.

44 THE EFFECT OF ANTRAL DENERVATION ON GASTRIC SECRETION IN THE DOG. *(E.)* Nundy, .; Baron, J. H. (Hammersmith Hosp., London, England). . *J. Surg.* 61(2):154-156, 1974.

e effect on gastric secretion of cutting the antral erves was studied in dogs with a previous complete roximal gastric vagotomy, with an incomplete proxi- al gastric vagotomy, and with otherwise intact agi. There was no change in insulin- and pentagas- rin-stimulated acid output in dogs with a previous agotomy. The dog with otherwise intact vagi showed o change in insulin-stimulated acid output but there as a diminished acid response to low doses of pen- agastrin. These results, if confirmed in man, ould suggest that the antral vagal nerves have no linically significant effect on gastric acid secre- ion.

445 GASTRIC H^+, Cl^-, AND PEPSIN SECRETION IN FISTULA DOGS WITH HISTAMINE, BETAZOLE, RIAZOLE, AND N-METHYLHISTAMINES. *(E.)* Hirschowitz, . I.; Hutchison, G. A. (Dept. Med., Univ. Alabama, irmingham). *Am. J. Physiol.* 226(3):656-661, 1974.

ix dogs with gastric fistula were stimulated dose esponsively in 6 or 7 successive 45 min steps with istamine (2-150 μg base/kg-h); 2 ring analogs; be- azole (30-3,000 μg/kg-h), and triazole (3-300 μg/ g-h); and 2 side-chain analogs; *N*-methylhistamine 6-60 μg/kg-h), and *N*-dimethylhistamine (3-160 μg/ g-h). Each experiment was duplicated. Dose-respon- ive volume, H^+ and Cl^- output, could be described by ichaelis-Menten-type kinetics from which can be alculated V_{max} and K_m (the dose giving 50% of V_{max} utput). For acid output with histamine, *N*-(Me)-his- amine, *N*-(Me)$_2$-histamine, betazole, and triazole, V_{max} was 18.0, 16.2, 17.9, 14.3, and 13.3 meq H^+/30 in, respectively, and K_m was 17.5, 14.4, 18.5, 597, and 23 μg/kg-h, respectively. The ring analogs, etazole and triazole, therefore, appear to be the less potent electrolyte stimulants. Pepsin was inimally stimulated by histamine or the methylhis- tamines, but was stimulated by betazole and by tria- zole. The peak pepsin output values were 4, 10, 12, 36, and 45%, respectively, of maximum rates with vagal stimulation.

3446 CYCLIC GMP RESPONSE IN VIVO TO CHOLINERGIC STIMULATION OF GASTRIC MUCOSA. *(E.)* Eichhorn, J. H.; Salzman, E. W.; Silen, W. (Harvard Med. Sch., Boston, Mass.). *Nature* 248(5445):238-239, 1974.

To investigate the possibility that cyclic guanosine 3',5'-monophosphate (cGMP) might be a mediator for cholinergic nervous stimuli in the stomach, an *in vivo* preparation making possible the direct stimulation of the vagus nerves was devised. Acid secretion was demonstrated by measurement of the pH of the gastric mucosal surface. Sham operations produced no change in mucosal cGMP content. Electrical stimulation for 1 minute of 30 pulses (10 ms, 22V) s^{-1} to the distal thoracic vagus nerves cut just above the diaphragm more than doubled mucosal cGMP in the fundus of the stomach but did not change antral mucosal cGMP. Pretreatment with i.v. atropine (0.2 mg/kg^{-1}), a cholinergic antagonist, prevented the increase in fundic mucosal cGMP. Infusion of ACh iodide (0.05 mg in 1 min) into the celiac artery produced a 2-fold increase in fundic mucosal cGMP and no change in the antrum. Vagal stimulation achieved by hypoglycemia after i.v. injection (0.6 units kg^{-1} in a bolus) of crystalline zinc insulin (blood sugar below 50 mg/100 ml in all dogs) caused a nearly 2-fold increase in fundic cGMP with no change in the antrum. The fundus was resected in 4 dogs with vagal innervation of the antrum preserved intact. After removal of this acid-secreting area, vagal stimulation still failed to alter antral mucosal cGMP. It is concluded that these data demonstrate an association between several types of cholinergic stimulation of the stomach *in vivo* and an increase in canine fundic mucosal cGMP. Possibly cGMP may serve as a second messenger for ACh, the first messenger of cholinergic stimuli.

3447 SALICYLATE EFFECTS ON GASTRIC ACID SECRETION. *(E.)* Glarborg Jorgensen, T.; Kaplan, E. L.; Peskin, G. W. (Rothschild Surg. Res. Lab., Chicago, Ill.). *Scand. J. Clin. Lab. Invest.* 33(1):31-38, 1974.

The effect of sodium salicylate on gastric acid secretion was studied in frog (*rana pipiens* or *rana catesbiana*) gastric mucosa *in vitro*, which allows continuous titration of secreted hydrogen ions. When added to either side of the membrane, sodium salicylate diminished both basal and pentagastrin-stimulated acid secretion in a dose-related manner. The dose of submucosal salicylate necessary to produce the same effect as mucosal side addition was approximately twice as high. It is concluded that the theory is supported that salicylate inhibition of acid secretion may be the result of changes in cell metabolism leading to local uncoupling of oxidative phosphorylation.

SECRETION AND METABOLISM

Pancreas

3461 EFFECTS OF STARVATION ON AMYLASE STORAGE IN MOUSE PANCREAS AND PAROTID GLAND: A BIOCHEMICAL AND MORPHOMETRIC STUDY. *(E.)* Carlsoo, B.; Danielsson, A.; Helander, H. F. (Dept. Histol., Anat., Univ. Umea, Sweden). *Acta Hepatogastroenterol.* 21(1):48-57, 1974.

Fasting-induced changes in the mouse exocrine pancreas and parotid gland were investigated. Pancreatic amylase content decreased from 20 to 9 U/mg tissue wet weight after a 12-hr fast, whereas parotid gland amylase increased from 6 to 10 U/mg tissue wet weight. There was a close correlation between the amylase content of the individual glands and the volume density of their secretory granules, as measured on electron micrographs. Similarly, a close correlation was demonstrated between amylase content and numbers of secretory granules/unit area. In the parotid gland the doubling of amylase content after fasting was paralleled by a doubling of the volume density of secretory granules. The number of granules increased by about 40%. This discrepancy is explained by the increased mean granule diameter observed after fasting (0.91 μ versus 0.77 μ in nonfasted animals).

462 THE EFFECTS OF GASTRIC EXCLUSION OPERATIONS ON PANCREATIC EXOCRINE SECRETION. *(E.)*
homas, J. W.; Mason, E. E. (Dept. Surg., Univ.
entucky, Lexington). *Surgery* 75(3):461-470, 1974.

hree dogs with pancreatic fistulas were subjected in
ccession to 66% gastric bypass, antral exclusion,
nd 66% gastric resection. Three feeding experiments
ere done after each operation. Each consisted of a
tandard meal and collection of nine 30-min samples
f pancreatic juice. The volume, bicarbonate, and
rotein content of each sample was determined. Pan-
reatic juice was continuously replaced into the
uodenum. The principal effect of the gastric ex-
lusion operations was on the pattern of secretion
ather than on the quantity of secretion. The effects
f gastric bypass were a late rise in volume secre-
ion and a 30-min delay in peak protein secretion.
owever, delay in the peak protein secretion follow-
g gastric resection was 60 min; therefore, the
mpairment in mixing of food and pancreatic juice
ould not be as great after gastric bypass as after
comparable gastric resection.

SECRETION AND METABOLISM

Hepatobiliary Tract

70 HISTODYNAMIC INTERPRETATION OF BILIARY EPITHELIO-MESENCHYMATOUS REACTIONS IN EX-
RIMENTAL CHOLESTASIS. *(E.)* Serrao, D.; Cardoso,
(St. John's Hosp., Asprela, Oporto, Portugal).
thol. Eur. 8(3):219-234, 1973.

gs were subjected to the following operative pro-
dures: total interruption of the terminal bile
ct, reproducing total cholestasis; segmental inter-
ption of the biliary tree, reproducing lobar chole-
asis; choledocho-caval anastomosis, producing chol-
ic saturation; partial ligature of the posterior
na cava thoracic segment, producing venolymphatic
asis; and cholestasis and hepatic venous stasis.
ese procedures resulted in accentuated cholestasis
all animals. Based on these and previous results,
is suggested that the connective atmosphere of the
liary ducts is really the supporting tissue of the
ribiliary lymphatic circulation which begins in a
pillary network connecting with the basal membrane
the third-order ducts, from the sites where
nalicula perforate Glisson's capsule and become ducts.
rther, the intrabiliary pressure, particularly the bilio-lymphatic reflux, associated with the general conditions of lymph drainage from the liver, is the principal factor involved in peribiliary mesenchymatous activation. Once initiated, this pressure soon becomes independent, progressing into irreversible fibrosis with portal hypertension.

3471 HEPATOMA--FOETAL Phe-tRNA ALSO PRESENT IN NORMAL RAT LIVER. *(E.)* Mushinski, J. F. (Natl. Cancer Inst., Bethesda, Md.). *Nature* 248 (5446):332-334, 1974.

Aminoacyltransfer(t) RNAs from mouse and rat tumors and normal tissues were compared using reversed phase chromatography on RPC-5 columns. The results showed an early eluting peak of phenylalanyl (Phe)-tRNA in Morris hepatomas but not in normal liver. Identical amounts of liver tRNA and hepatoma tRNA were then aminoacylated with DEAE and G-10 enzymes from liver and tumor. The G-10 enzymes increased the total incorporation into the major peak of Phe-tRNA 2- to 3-fold over the DEAE enzymes, while increasing the incorporation into the minor peak more than 15-fold; thus a minor peak not seen in liver tRNA charged with aged DEAE enzyme became very prominent when G-10 enzyme was used. Although there was a distinct difference in the prominence of the minor Phe-tRNA from normal liver and from hepatomas no matter which aminocylating enzyme was used, it was not possible to refer to a tumor-specific peak of Phe-tRNA. No increases in the minor Phe-tRNA were found in regenerating liver tested 1, 2, 3, 7, or 10 days after partial hepatectomy. The data indicate that although both the minor Phe-tRNA and α-fetoprotein may represent increased activation of genes primarily associated with embryogenesis or rapid growth conditions, a direct correlation does not exist between them.

3472 LIVER-SPECIFIC ANTIGENS OF DIFFERENT SPECIES. II. LOCALIZATION OF A MEMBRANE ANTIGEN AT CELL SURFACE OF ISOLATED HEPATOCYTES. *(E.)* Hopf, U.; Meyer Zum Buschenfelde, K. H.; Freudenberg, J. (2nd Dept. Intern. Med., Univ. Mainz, Germany). *Clin. Exp. Immunol.* 16(1):117-124, 1974.

The livers from Sprague-Dawley rats and young rabbits were kept moist at 37 C. The livers were perfused for 5 min with physiological saline followed by EMBA (Eagle's medium plus 2.5% bovine serum albumin) for a similar period. The perfusion rates were maintained at 18 ml/min for the rat and 24 ml/min for the rabbit livers. The tissue was then cut into small pieces, incubated in 20 ml EMBA in an oxygen atmosphere at 37 C and shaken in a waterbath for 5 min. The cell suspension was filtered through nylon wool. Human hepatocytes were isolated similarly, the liver tissue having been obtained by needle biopsy. When studied by phase contrast microscopy or by the luciferase test, the preparation contained about 95% live hepatocytes. Immunofluorescence studies located the lipoprotein at the cell surface of isolated hepatocytes. Indirect immunofluorescence confirmed results obtained by passive hemagglutination that suggest this is an organ-specific membrane lipoprotein, not species-specific. Cryostat sections of kidney, thyroid, and skeletal muscle showed no membrane fluorescence when monospecific heteroimmune sera were applied. The findings of this study will be helpful in determining the mechanism of different cytotoxic immune reactions under defined conditions.

3473 INCREASE IN THE PHAGOCYTIC ACTIVITY OF THE RETICULOENDOTHELIAL SYSTEM IN THE LIVER AFTER SPLENECTOMY. *(It.)* Petrelli, F.; Marsili, G. (Inst. Gen. Physiol., Univ. Camerino, Italy). *Boll. Soc. Ital. Biol. Sper.* 48(22):911-914, 1972.

The phagocytic activity of the liver was investigated in female splenectomized Wistar WMZ rats by histological examination of the liver and by analysis of the kinetics of the clearance of colloidal carbon from the blood. While no differences were found between intact controls and rats splenectomized 24 hr previously, carbon disappeared more rapidly from the blood of rats splenectomized 60 days before. In these rats Benacerraf's phagocytic index was significantly increased. This increase was not due to a difference in the relative weight of the liver, but to an increase in the activity of the reticulohistiocytary system in the liver as a result of hyperplasia. These splenectomized rats had larger numbers of Kupffer cells in their livers than controls, and the Kupffer cells were filled with carbon particles.

3474 PREVENTION OF HALOTHANE INDUCED CHANGES IN RAT LIVER ENZYMES BY 3-AMINO-1,2,4-TRIAZOLE. *(E.)* Langhans, W.; Schimassek, H. (Inst. Biochem., Univ. Heidelberg, Germany). *Biochem. Pharmacol.* 23(2):403-409, 1974.

It has already been shown that 3-amino-1,2,4-triazole inhibits the biological transformation of halothane in liver. Inhibition of the transformation of halothane prevents some of the changes in liver metabolism observed after halothane treatment. Changes in enzyme activities were measured as sensitive indicators. Halothane and its stable metabolite trifluoracetate greatly increased the activity of the mitochondrial glycerol-3-phosphate oxidase. Pretreatment of male Wistar rats with aminotriazole (75 mg/100 g i.p.) inhibited the activity increase caused by halothane (1 vol% halothane-O_2 1 hr/day for 14-17 days), but not by trifluoracetate (130 μM/100 g in drinking water). Aminotriazole also prevented the increase in the activity of malic enzyme, reduced nicotinamide adenine dinucleotide diphosphate-oxidase, and lactate dehydrogenase produced by halothane treatment. The induction of glycerol-3-phosphate oxidase was not counteracted by actinomycin D because actinomycin itself increased the activity of glycerol-3-phosphate oxidase.

3475 PREVENTION OF CARBON TETRACHLORIDE-INDUCED NECROSIS BY INHIBITORS OF DRUG METABOLISM--FURTHER STUDIES ON THEIR MECHANISM OF ACTION. *(E.)* Castro, J. A.; De Ferreyra, E. C.; De Castro, C. R.; De Fenos, O. M.; Sesame, H.; Gillette, J. R. (Lab. Chem. Bio-Toxicol., CITEFA, Buenos Aires, Argentina). *Biochem. Pharmacol.* 23(2): 295-302, 1974.

Liver necrosis caused by carbon tetrachloride is known to be decreased by the administration of 2-diethylaminoethyl 2,2-diphenylvalerate, ethyl 2-diethyl-aminoethyl-2-phenyl-2-ethyl malonate, ethyl N-(2-diethylaminoethyl)2-phenyl-2-ethyl malonate, ethyl 2-diethylaminoethyl 2-ethyl-2-butyl malonate, 2-diethylaminoethyl 2-phenyl (2-propene) 4-penten-1-oate, 2,4,-dichloro-6-phenyl phenoxyethyl diethylamine, and 2,4-dichloro-6-phenyl phenoxyethylamine. Although these substances inhibit cytochrome P-450 dependent drug-metabolizing enzymes in liver microsomes, they apparently do not evoke their protective effects by slowing the elimination of carbon tetrachloride. In fact, 2-diethylaminoethyl 2,2-diphenylvalerate (50 mg/kg i.p.), but none of the other inhibitors, partially prevented the impairing effects of carbon tetrachloride (2.5 ml/kg p.o. or 20 or 30% in olive oil i.p.) on cytochrome P-450 in Sprague-Dawley rat liver. Although 2-diethyinoethyl 2,2-diphenylvalerate markedly decreased e liver necrosis and the rise in serum isocitrate ydrogenase caused by carbon tetrachloride, it ly partially prevented the carbon tetrachloride-duced decrease in body temperature. The protec-ve effect of 2-diethylaminoethyl 2,2-diphenyl-lerate can be attributed to the inhibition of crosomal enzymes that catalyze the conversion of bon tetrachloride to an active metabolite.

6 MICROSOMAL ENZYME ACTIVITY IN PERFUSED RAT LIVER.

(E.) Bartosek, I.; Guaitani, Garattini, S.; Simonazzi, I. ("Mario Negri" t. Pharmacol. Res. Milan, Italy). *Biochem. rmacol.* 23(3):599-605, 1974.

activities of microsomal enzymes were observed g perfusion of livers isolated from both normal phenobarbital treated male Sprague-Dawley rats. hydroxylation of aniline (5 μM) and the *O*-de-hylation of *p*-nitroanisol (1.5 μM) did not de-ase substantially (10%) in the 9000 g fraction pared from livers perfused for 4 hrs. *N*-demethyla-n of aminopyrine (5 μM) was reduced by 60% in same experimental conditions. A similar de-ase of *N*-demethylation was also observed when ers were isolated from animals treated with nobarbital (50 mg/kg i.v.). The content of cyto-ome P-450 in the microsomes was stable during -hr perfusion of isolated liver. The decrease of emethylation of aminopyrine could be partly re-red by the simultaneous infusion of nicotinic d (0.2 mM), which is a precursor of nicotinamide nine dinucleotide and nicotinamide adenine dinu-otide phosphate biosynthesis. Accurate control experimental conditions is a prerequisite when technique of perfusion of isolated liver is d for studies on drug metabolism. These results erline the problem that lack of necessary cofac-s may change the parameters of drug transforma-n.

7 EFFECTS OF DIETARY CHOLESTEROL ON BILE ACID SYNTHESIS IN LIVER AND HEPATOMAS.

Bricker, L. A.; Marraccini, J. V.; Rosenblatt, Kozlovskis, P. L.; Morris, H. P. (Univ. Miami Med., Florida). *Cancer Res.* 34(3):449-453, .

effects of cholesterol feeding on bile acid pro-ion *in vitro* in liver were contrasted with se in a strain of Morris hepatoma active in sterol hesis. The Morris hepatoma 3924A tumors were splanted in the right thighs of recipient ACF/ rats. Animals were kept on either a normal na rat chow low-cholesterol diet or a high esterol diet, consisting of 5% cholesterol and oleic acid, to which sufficient cholesterol-1α, H had been added to give the cholesterol a ific radioactivity of 3750 dpm/μmole. Pretreat-with the high-cholesterol diet suppressed the ity of the liver to convert acetate to bile . This suppressed liver from the cholesterol-animal converted dietary sterol (instead of ex-ally added acetate) to bile acid. When 500 mg lices of Morris hepatoma are incubated with acetate-2-^{14}C, this highly malignant, undifferentiated adenocarcinoma of liver incorporates acetate into bile acid, and in amounts comparable to that of liver. There is no suppressive effect of dietary cholesterol on this synthetic process. This tissue was essentially unable to use dietary cholesterol as a precursor for synthesis of its own bile acid, despite its easy accessibility in the circulation *in vivo*. It is concluded that bile acid production *de novo* from acetate in liver is suppressible by dietary cholesterol in a fashion comparable with, and related to, the cholesterol negative feedback phenomenon. In liver, a dual, reciprocating precursor supply is available for bile acid formation. Dietary cholesterol functions in the presence of blockaded sterol synthesis as the sole precursor of bile acid. In the presence of a high-cholesterol diet, liver has the ability to convert mevalonate and stored dietary cholesterol simultaneously to bile acid. The Morris hepatoma 3924A is active in bile acid production from both acetate and mevalonate, but these syntheses are unaffected by dietary cholesterol. Dietary cholesterol cannot itself be utilized by the tumor for bile acid synthesis.

3478 A NOVEL METHOD FOR THE SEPARATION AND IDENTIFICATION OF BILE ACIDS AND PHOSPHOLIPIDS OF BILE ON THIN-LAYER CHROMATOGRAMS.

(E.) Goswami, S. K.; Frey, C. F. (Wayne County Gen. Hosp., Eloise, Mich.). *J. Chromatogr.* 89(1):87-91, 1974.

A method is described which successfully accomplishes the separation of several classes of bile lipids on a single plate making possible a direct comparison between different bile lipid components such as cholesterol, free and conjugated bile acids, lecithin and lysolecithin. Bile samples were collected from gallstone patients by puncture of the gallbladder during operation. The spray reagent was the same as used for phospholipid detection. About 10- μg samples of each of free and conjugated bile acids and phospholipids were applied as spots of 4 mm diameter at 1.5 cm above the bottom edge of the plate. Volumes of 0.5-1.0 μl of the bile samples were applied directly to the plate. The plate was then placed in a chromatographic chamber previously saturated with the solvent system isooctane-isopropyl alcohol-ethyl acetate-acetic acid (40:20:10:19, v/v) at room temperature. After the center of the solvent front reached the 13-cm mark, the plate was taken out of the chamber and dried with cold air for 2 to 3 min. The plate was next placed in a second chamber and developed with the solvent system chloroform-methanol-water (65:35:4, v/v) up to the 6-cm mark and taken out of the chamber. Bile samples from gallstone patients and pure bile acids, conjugated and unconjugated, cholesterol, lysolecithin, and lecithin were examined by this method. Whatever might be the difference of R_F values, the compounds tested can be identified by their characteristic colors. The blue phospholipid color and the pink cholesterol color appear within 5-7 min of heating in the oven; the other bile acid colors appeared after that. All the colors stand out clearly in an almost white background. Lysolecithin and lecithin are blue; taurocholic acid, taurodeoxycholic acid, glycocholic acid, and glycodeoxycholic acid are greyish green; taurochenodeoxycholic acid, glycochenodeoxycholic acid, and chenodeoxycholic acid are purple; cholic acid is greenish yellow; deoxycholic acid is yellow; lithocholic acid is light purple; and cholesterol is pink and turns greenish grey.

3479 EFFECT OF ETHANOL ON FATTY ACID OXIDATION IN THE PERFUSED LIVERS OF STARVED, FED, AND FAT-FED RATS.

(E.) Fellenius, E.; Kiessling, K. H. (Inst. Zoophysiol., Univ. Uppsala, Sweden). *Acta Chem. Scand.* 27(8):2781-2790, 1973.

On the basis of measurements of oxygen uptake, ethanol and oleate removal, and the production of ketone-bodies and acetate by the perfused liver, the effect of ethanol (10 mM) on the flow through the citric acid cycle and the β-oxidation pathways was calculated. Studies were carried out with livers from fed, 48-hr starved, and fat-fed female Wistar rats. The high fat diet consisted of 90 parts margarine and 10 parts casein, and was supplemented with salts and vitamins. Ethanol depressed flow through the citric acid cycle by 40 to 60% depending on the nutritional state of the rat. The addition of pyruvate partly overcame this inhibition. The pathway of β-oxidation was also blocked by the addition of ethanol although, except for the fat-fed rats, ketone-body production was unaltered. The results suggest that if inhibition of the citric acid cycle by ethanol favors an accelerated rate of ketogenesis, this effect may be concealed by a block in β-oxidation which limits the supply of acetyl-coenzyme A for ketone-body formation. Ethanol did not stimulate triglyceride synthesis in livers from animals on a high-fat diet, while the β-oxidation pathway was greatly inhibited. The fraction of fatty acid undergoing esterification depends primarily on the level of α-glycerophosphate.

3480 EFFECT OF DIETARY 1,3-BUTANEDIOL ON IN VITRO FATTY ACID SYNTHESIS AND MALIC ENZYME ACTIVITY IN RAT LIVER AND ADIPOSE TISSUE.

(E.) Romsos, D. R.; Sasse, C.; Leveille, G. A. (Dept. Animal Sci., Univ. Illinois, Urbana). *J. Nutr.* 104(2):202-209, 1974.

Diets containing graded levels of 1,3-butanediol (BD) substituted for approximately equal amounts of glucose energy were fed to male, Sprague-Dawley rats. Body weight gain was not affected by addition of 10 parts (17% of dietary energy) BD to the diet; however, addition of 15 parts BD (25% of dietary energy) or more did depress weight gain. Plasma β-hydroxybutyrate and acetoacetate levels were elevated as dietary BD was increased. Increasing the BD content of the diet decreased plasma glucose, insulin, and triglyceride levels. Plasma free fatty acids were increased by addition of BD to the diet. Hematocrit was increased slightly in rats fed the BD-containing diets and may have been related to the increased rate of urination associated with elevated plasma ketones. Hepatic rates of *in vitro* fatty acid synthesis were markedly depressed when BD was added to the diet. The *in vitro* rates of fatty acid synthesis in adipose tissue were not affected by dietary BD. Malic enzyme activity was depressed in both liver and adipose tissue only when high levels of BD were added to the diets. It is suggested that dietary BD affects hepatic fatty acid synthesis in the rat by its effect on the hepatic reduced nicotinamide adenine dinucleotide/nicotinamide adenine dinucleotide ratio.

3481 HEPATIC ERYTHROPOIETIN PRODUCTION IN THE LEAD-POISONED RAT.

(E.) Schooley, J. C.; Mahlmann, L. J. (Lawrence Radiat. Lab., Univ. California, Berkeley). *Blood* 43(3):425-428, 1974.

Extrarenal erythropoietin production was studied in lead-injected male Sprague-Dawley rats exposed to hypoxia (5 hr at 22,000 ft) immediately after or 1 day after nephrectomy. Total erythropoietin production, as a result of hypoxic exposure, was not altered when lead (40 mg/kg i.v.) was injected 1 day before the 5-hr exposure. The production of the hormone by rats exposed to hypoxia immediately after nephrectomy was 4.5 times greater than in rats injected with lead 1 day before nephrectomy. Lead injection without a hypoxic exposure did not increase the serum erythropoietin level. The production of erythropoietin in the lead-injected anephric rats was almost completely prevented by partial hepatectomy or injection of actinomycin D (0.5 μg/g i.v.). Serum erythropoietin levels were not elevated in anephric hepectomized rats when the hypoxic exposure was increased to 28,000 ft or when the rats were bled (1.5 ml/100 g) before exposure to 22,000 ft. The increased extrarenal erythropoietin production in lead-poisoned animals suggests that processes involved in biogenesis of the hormone are increased above normal in the liver to compensate for the kidney dysfunction. Similar changes in the site of production or activation of the hormone may occur in renal disease.

3482 DEVELOPMENTAL CHANGES IN STEROL BIOSYNTHESIS FROM ACETATE AND MEVALONATE IN RAT LIVER.

(E.) Wrobel, J.; Boguslawski, W.; Michalska, L.; Niemiro, R. (Med Sch., Gdansk, Poland). *Int. J. Biochem.* 4(24):565-568, 1973.

Sterologenesis in the developing rat liver was investigated both *in vivo* and *in vitro* in Wistar albino rats of both sexes. For liver sterol synthesis *in vivo*, rats were given (I-^{14}C)acetate (1.0 μc/g) with (2^{-3}H)mevalonate (0.5 μc/g) in 0.9% NaCl by i.p. injection. Fetuses were kept alive in a thermostat set at 37 C while carrying out the experiment. Exactly 2 hr later the rats were killed and their livers were quickly removed. For liver sterol synthesis *in vitro*, the livers from at least 5 litter-mate rats were routinely pooled. Liver tissue was incubated at 37 C for 2 hr with 3.0 μc (I^{-14}C)-acetate and 0.9 μc. (2^{-3}H)mevalonate in 1.0 ml of Krebs-Ringer phosphate buffer, pH 7.4. There was a higher incorporation of (I^{-14}C)acetate into sterols in the 19-day fetus. This incorporation rose at birth, decreased sharply in the 2-day-old animal, and remained low between days 2-18 of postnatal life. There was a sharp increase in the incorporation of (I^{-14}C)acetate in the 22-day-old rat and the level was maintained in the 1-month-old-rat. The incor-

ation of $(2^{-3}H)$mevalonate into liver sterols was
h both in the 19-day-old fetus and in the 1-day-
rat, decreased 3-fold in the 2-day-old animal
remained essentially on the same constant level
ween days 5-30 of postnatal life. The effect of
on liver sterologenesis was similar *in vitro*.
the 2 to 18-day-old rat, the incorporation of $(I^{-14}C)$-
tate into digitonin-precipitable sterols was about
times lower than in the 19-day-old fetus and in
24 to 31-day rat. The incorporation of $(2^{-3}H)$me-
onate into digitonin-precipitable sterols was
entially constant between days 2-31 of postnatal
e. The incorporation of $(2^{-3}H)$mevalonate in the
-day-old fetus was about 2 times higher than in
2-day-old rat and in older animals. It is con-
ded that the rate of liver sterologenesis differs
kedly during pre- and postnatal development.
o, the developmental pattern of acetate incorpor-
ion into sterols is different from that of meva-
ate.

33 THE INFLUENCE OF ETHANOL-INDUCED CHANGES OF THE α-GLYCEROPHOSPHATE LEVEL ON HEPATIC
GLYCERIDE SYNTHESIS.

(E.) Fellenius, E.; Bengts-
, G.; Kiessling, K. H. (Inst. Zoophysiol., Univ.
sala, Sweden). *Acta Chem. Scand.* 27(8):2893-
1, 1973.

correlation between the level of α-glycerophos-
te and hepatic triglyceride synthesis was studied
livers from female Wistar rats. Livers were
fused *in situ* with and without oleate (2 mM) in
medium and the hepatic content of α-glycerophos-
te was varied by using livers of rats in differ-
nutritional states and by adding ethanol (10 mM),
uvate (1.93 M) or glycerol (0.33 M) to the perfu-
e. Changes in triglycerides were not a function of
concentration of α-glycerophosphate in the ab-
ce of oleate. In the presence of oleate, alone or
h other substrates, a correlation could be ob-
ved. Pyruvate tended to inhibit the ethanol-
uced increase of α-glycerophosphate and malate.
ate also decreased the ethanol-induced accumula-
n of α-glycerophosphate in the livers of starved
s but not in those of rats on normal diet. The im-
tance of the availability of proton acceptors for
regulation of the level of α-glycerophosphate is
cussed. The level of α-glycerophosphate may in-
ence net triglyceride synthesis. Factors that in-
ence the concentration of α-glycerophosphate may
the flux of α-glycerophosphate into mitochondria,
supply from glycolysis, gluconeogenesis, lipid
abolism, the pentophosphate pathway, the kinetic
avior of α-glycerophosphate dehydrogenase, the
take of glycerol from the blood, and finally the
ox state, or the availability of different proton
ceptors. Information on the interrelation between
glycerophosphate, malate, and lactate is of impor-
ce for a knowledge of the role of the availability
proton acceptors. It is possible that the β-hy-
oxybutyrate dehydrogenase is more important than
malate dehydrogenase for the reoxidation of
glycerophosphate under the present experimental
nditions. The capacity of the isolated liver
tochondria of rats fed a high-fat diet to oxidize
glycerophosphate was twice as great as that of
liver mitochondria of rats on a normal diet.
The result indicates a relation between lipid metabolism and the activity of the mitochondrial α-glycerophosphate dehydrogenase.

3484 REDUCTION OF ACUTE ALCOHOLIC INTOXICATION BY α AMINO ACIDS: GLYCINE AND SERINE.

(E.) Blum, K.; Wallace, J. E.; Friedman, R. N. (Univ. Texas Med. Sch., San Antonio). *Life Sci.* 14(3):557-565, 1974.

The ability of glycine and of serine to protect Sprague-Dawley rats from ethanol induced motor impairment was determined by pretreating the animals with these drugs (20.0 mM/kg p.o.), administering ethanol (108.7 mM/kg) 30 min later, and evaluating performance on a rotor-rod test at 30 min and 2 hr post-ethanol. Performance of the glycine and serine-pretreated rats was significantly superior to that of controls at the 30-min post-ethanol trial but not at the 2-hr trial. Blood-alcohol levels measured at the times of the trials corresponded with the behavioral performance. The levels were significantly depressed during the 30-min post-ethanol trials for both the glycine- and serine-pretreated groups. These findings provide evidence that glycine- and serine-induced protection against the described motor impairments caused by ethanol may be due to a suppression of the rate of absorption of ethanol from the gastrointestinal tract.

3485 GLUCAGON STIMULATION OF HEPATIC GLUCONEOGENESIS IN RATS FED A HIGH-PROTEIN, CARBOHYDRATE-FREE DIET.

(E.) Eisenstein, A. B.; Strack, I.; Steiner, A. (Brooklyn-Cumberland Med. Ctr., N.Y.). *Metabolism* 23(1):15-23, 1974.

The effects of glucagon (1 μg), dibutyryl cyclic AMP (DB-CAMP, $10^{-5}M$), and insulin (1U) on hepatic gluconeogenesis were examined in rats fed either a control diet, or a diet high in protein with no carbohydrates (HP). In perfused liver of control male Holzman rats, alanine conversion to carbohydrate amounted to 20.39 μmole/100 g/90min. Gluconeogenesis was increased to 35.14 by glucagon; to 31.40 by DB-CAMP, and suppressed to 14.56 by insulin. When both glucagon and insulin were added to the medium, only the stimulatory action of glucagon was evident. In perfused liver of HP-fed rats, alanine incorporation into carbohydrate totalled 51.79. Gluconeogenesis was elevated by glucagon to 65.23, by DB-CAMP to 62.27, and was unaffected by insulin, 49.73. In the presence of both glucagon and insulin, only the glucagon effect was apparent. Alanine, lactate, and pyruvate concentrations were reduced in HP liver, while phosphoenolpyruvate (PEP) was increased, findings that suggest enhanced conversion of pyruvate to PEP. Fructose diphosphate concentration was normal but fructose-6-phosphate was greatly elevated. Similar changes in hepatic metabolites have been found following exposure of normal liver to glucagon. Plasma insulin values were not altered by HP feeding. Plasma-glucagon levels were higher in HP rats than in controls. When the molar ratio of insulin to glucagon in plasma was calculated, the value in HP-fed rats was reduced. Liver cyclic AMP was greater in HP-fed rats than in controls, a finding that indicates that the liver was exposed to an increased amount of glucagon. It is concluded that increased glucagon secretion is responsible for the enhanced hepatic gluconeogenesis which occurs in HP-fed rats.

3486 BIOSYNTHESIS OF PROTEINS WHICH APPEAR IN RAT SERUM DURING LIVER REGENERATION.

(Ukr.) Polishchuk, A. S.; Danko, I. M.; Korotkoruchko, V. P.; Bogdan, I. P. (O. V. Palladin Inst. Biochem., Kiev, USSR). *Ukr. Biokhim. Zh.* 45(5):559-564, 1973.

The composition of serum proteins was investigated and the rates at which various protein fractions incorporated ^{14}C-1-glycine were measured in male rats 24 hr after partial hepatectomy performed by the method of Higgins and Anderson. Serum proteins were separated by elution from DEAE-Sephadex A-50 columns and were identified as α-, β-, and γ-globulin and albumin by their electrophoretic mobilities. During liver regeneration the rate at which serum γ- and α-globulin incorporated ^{14}C-1-glycine was 63% and 27%, resp., greater than the corresponding serum protein fractions from intact controls. The β-globulin and albumin fractions from hepatectomized rats incorporated this labeled amino acid more slowly than the corresponding serum protein fractions from controls. Investigations of ^{14}C-1-glycine incorporation into subfractions of γ- and α-globulins, obtained by step-wise elution from columns of DEAE-cellulose, showed that protein synthesis occurred most rapidly in subfractions which gave a positive (unspecified) precipitation reaction. These findings also suggest that liver regeneration is accompanied by rapid synthesis of serum proteins which are characteristic for this state.

3487 THE CHOLERETIC ACTION OF ETHACRYNIC ACID IN THE RAT.

(Ger.) Czok, G.; Schulze, P. J. (Pharmacol. Inst., Univ. Hamburg, Germany). *Arzneim. Forsch.* 23(12):1712-1716, 1973.

The relation between the extent and duration of increased bile flow and the dose of ethacrynic acid was established and the composition of bile obtained after administration of this agent was determined. When placed in the lower part of the duodenum through a catheter, 25, 50, 100, and 200 mg/kg of ethacrynic acid increased the bile output of male urethan-anesthetized Wistar rats by 25%, 64%, 114%, and 164%, resp. Cholestasis, which was usually fatal, occurred 2 hr after administration of 200 mg/kg. The maximum increase in bile flow, which occurred 1 hr after administration of ethacrynic acid, was accompanied by an increase in dry weight and K$^+$ concentration while the NA$^+$ and Cl$^-$ concentrations remained essentially unchanged. Although the amount of bile salts was increased, their concentration was decreased at this time. One hr after intraduodenal administration of ^{3}H-labeled ethacrynic acid, 26.44% had been excreted in the bile and 5 hr later 37.56% had been excreted. After 5 hr 7.09% of the activity was found in the urine and 18.5% was excreted from the gastrointestinal tract. In addition to unchanged ethacrynic acid, 3 metabolites were found in the bile during the first hr after its administration. Only one metabolite, which was not present in the bile, was detected in the urine. Since a large percentage of ethacrynic acid is excreted in the bile, it is suggested that this agent causes osmotic choleresis. The increased K$^+$ concentration of the bile is explained by the loss of this electrolyte from the cells due to the specific action of ethacrynic acid on the cell.

3488 AMYLASE ACTIVITY OF THE BILE AND LIVER IN ANIMALS AFTER RESECTION OF THE SMALL INTESTINE.

(Rus.) Talanina, L. Kh.; Kadyrov, M. Kh. (Tashkent Med. Inst., USSR). *Fiziol. Zh. SSSR* 59(11):1753-1756, 1973.

Amylase activity was measured in gallbladder bile from dogs and in liver homogenates from rats before and at various periods after resection of the proximal or distal half of the small intestine. Significant increases occurred in bile secretion and total amylase activity of bile from dogs which had undergone resection of the small intestine. This increase was more pronounced and lasted for a longer time when the distal half of the small intestine was resected. After resection of the proximal half of the small intestine of rats, amylase activity in liver homogenates increased less but the increase lasted for a longer period than when the distal half of the small intestine was resected. These findings and literature data suggest that increases in the amylase activity of the bile and liver after resection of parts of the small intestine are associated with disturbances in metabolic processes in the body and indicate that changes have occurred in liver function.

3489 EFFECT OF STARVATION ON THE QUANTITATIVE CELL STRUCTURE OF RAT LIVER CELLS. II. CHRONIC PARTIAL STARVATION.

(Ger.) Riede, U. N.; Hodel, J.; Matt, C. V.; Rasser, Y.; Rohr, H. P. (Inst. Pathol., Univ. Basel, Switzerland). *Beitr. Pathol.* 150(3):246-260, 1973.

A quantitative morphological analysis was made of cells in the hepatic parenchyma of 3 male Fischer rats given only 1 g/day of Altromin-R standard diet for 6 weeks and of 3 controls. Chronic partial starvation decreased the volume of single hepatocytes by 50% and doubled the volume percent of the nucleus per cell without any change occurring in the volume of single nuclei. A 75% decrease occurred in the number of mitochondria, while the mitochondrial volume increased 4-fold and the volume percent of mitochondria per cell doubled. The area of the cristae in each cell decreased by 1/3 and the volume of the mitochondrion decreased by 1/2. The number of microbodies per cell decreased by 40%, while no change occurred in the microbody volume. A 50% decrease occurred in the volume percent of the rough endoplasmic reticulum per unit volume hepatocyte, while the membrane area of the rough and smooth endoplasmic reticula per hepatocyte decreased by 1/3. No appreciable changes occurred in the volume percent of lysosomes or the volume percent of the Golgi apparatus per cell. The formation of megamitochondria, which contained large amounts of matrix and small areas of cristae,

icates that the chondriome had undergone functional
rganization during chronic partial starvation.
s is probably due to fusion of mitochondria. Great
reases in the areas of both rough and smooth
oplasmic reticula indicate that both synthetically
metabolically active cell compartments were
uced to a functioning minimum. Because of this,
production of new microbodies from the rough en-
lasmic reticulum was inhibited so that a decrease
urred in the number of microbodies per hepatocyte.

0 DEVELOPMENTAL CHANGES IN MOUSE LIVER ALCOHOL DEHYDROGENASE. *(E.)* Krasner, J.;
ksson, M.; Yaffe, S. J. (Sch. Med., State Univ.
York, Buffalo). *Biochem. Pharmacol.* 23(3):519-
, 1974.

kinetic parameters and electrophoretic properties
adult and newborn mouse alcohol dehydrogenase were
died in Cobbs Swiss-Webster mice (Charles River).
ohol dehydrogenase activity, at varying ethanol
centrations, in the supernatant fraction of liver
ogenates was determined by recording the genera-
n of reduced nicotinamide adenine dinucleotide
340 nm. The alcohol dehydrogenase activity was
er in the newborn than in the adult mouse. The
ctrophoretic pattern of adult and newborn mouse
ohol dehydrogenase showed migration toward the cath-
. This electrophoretic pattern is only seen when
shly prepared homogenate is used; when the homogen-
is stored frozen overnight, this electrophoretic
tern is not seen. A control without added alco-
showed very little activity even after a pro-
ged incubation. Residual alcohol in the Cellogel
brane may have been responsible for the appearance
this slight activity.

1 ULTRAMICROSCOPIC STUDY OF THE BILE LIPOPROTEIN COMPLEX. *(E.)* Nalbone, G.;
ont, H.; Domingo, N.; Lairon, D.; Pautrat, G.;
ton, J. (Res. Unit. Digestive Pathol., I.N.S.E.R.M.,
seille, France). *Biochimie* 55(11-12):1503-1506,
3.

ctron microscopy data are presented that dis-
minate between mixed micelles and bile lipids and
vide an additional argument in favor of the lipo-
tein nature of the lipid associations in bile.
an gallbladder bile samples are obtained by pre-
rative puncture, while samples of sheep's gall-
dder bile are taken immediately after the animal
been sacrificed. Gel filtration is carried out
room temperature. Lecithins, total bile salts,
cholesterol are measured in the samples and the
ctions collected after gel filtration. The nega-
e staining technique is used on the native sam-
s of bile and synthetic micelles, as well as on the
l of collected lecithin-containing fractions. As
ule, it is not possible to detect any structure
direct examination of native samples of bile and
thetic mixed micelles. The images obtained from
h synthetic micelles and bile do not represent
native state of organization and identity of bile
synthetic micelles cannot be established on the
is of the images seen. Gel filtration, disso-
ting the bile salts from the lecithins and cholesterol, thus makes it possible to eliminate the artefacts due to detergents on negative staining. On gel filtration in the presence of NaCl, the lecithins and cholesterol in the synthetic mixed micelles are eluted with the first void volume; the bile salts, totally dissociated from the lecithins, are eluted with 2.5 Vo. The elution volume of the lecithins, cholesterol and bile salts in the samples of bile are identical with those for the synthetic mixed micelles. The bile pigments are eluted in the same fractions as bile salts. The polypeptide fraction is found only in the fraction containing the bile lecithins. The addition of albumin in a final concentration of 5 g/liter to the synthetic mixed micelles alters the elution pattern of lecithins, 60% being eluted with the first void volume and the remaining 40% at 2 Vo, at the same time as albumin. Bile salts are eluted with 2.5 Vo.

3492 RELATIONSHIP OF SERUM TRIGLYCERIDE LOWERING TO CHANGES IN HEPATIC COMPOSITION INDUCED BY DIFFERENT CLASSES OF DRUGS. *(E.)* Dalton, C.; Hope, W. C.; Hope, H. R.; Sheppard, H. (Hoffmann-La Roche, Inc., Nutley, N.J.). *Biochem. Pharmacol.* 23(3):685-696, 1974.

Dose-related serum triglyceride lowering has been demonstrated in the male albino rat with the microsomal enzyme inducers phenobarbital, 5,5'-diphenyl-2-thiohydantoin, and chlorcyclizine (50 mg/kg/day for 9 days, p.o.) and with the clinically tested anti-hyperlipidemic agents clofibrate (250 mg/kg/day for 9 days) 1-methyl-4-pi-peridyl bis(*p*-chlorophenoxy) acetate, and 2-methyl-2-[*p*-(1,2,3,4-tetrahydro-1-naphthyl)-phenoxy] propionic acid (50 mg/kg/day for 9 days). With both classes of drugs, serum lipid lowering was accompanied by hepatomegaly due to an increase in liver protein and phospholipid. Hepatomegaly was reversible upon cessation of drug treatment. The anti-hyperlipidemic drugs caused an increase in microsomal *N*-demethylase activity but this was slight when compared with the induction produced by known microsomal enzyme inducers. Examination of the subcellular compartments indicated that even though both mitochondrial protein and phospholipid were increased with all the agents studied, the dominant change in the case of the microsomal enzyme inducers was in the microsomal compartment, whereas the anti-hyperlipidemic agents induced a larger increase in the mitochondrial fraction. The total accumulation of new membrane material, however, was similar for both classes of drugs. These data demonstrate that 2 classes of drugs which produce hepatomegaly through a proliferation of intracellular membranes also lower serum triglyceride levels.

3493 STUDY OF THE UPTAKE AND OUTPUT OF MACROMOLECULES IN THE ISOLATED RAT LIVER: RELATION TO PERFUSION CONDITIONS. *(Ger.)* Jahn, W.; Lengsfeld, A. (Max Planck Inst. Med. Res., Heidelberg, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 281(2):241-256, 1974.

When livers from fed male Wistar rats were perfused with a fluid containing albumin or dextran, many vacuoles appeared in parenchymal cells 5-60 sec after the posthepatic pressure had been increased to 10 cm H_2O. These vacuoles first appeared on the sinusoidal side of the parenchymal cells, and some opened into Disse's spaces. Most cell structures remained intact, but a large decrease occurred in the number of microvilli. Within 50-60 min after circulation was normalized, the number of vacuoles had decreased and the number of microvilli had increased. When albumin was present in the perfusion fluid, vacuoles were filled with flocculent material, but when dextran was added, little or no electron-dense material was found in the vacuoles. Membranous structures were occasionally present in vacuoles produced by either dextran or albumin. Qualitatively similar reactions occurred when congestion was induced in the liver by blocking both ends of the vena cava for 5 min while perfusing at constant pressure (20 cm H_2O). The liver first took up water from the perfusion fluid and, after 50 min, released it. This process was associated with spontaneously reversible release of potassium from the liver. Measurements made with ^3H-dextran in the perfusion fluid revealed that the intracellular space had increased by 52 ± 8 µl/g and the dextran content by about 200 µl/g perfusion fluid after 50 min of congestion. When congestion was produced in the liver by increasing the posthepatic pressure, about half of the accumulated dextran was released within 5-10 min; much less albumin was released under these conditions. Both the uptake and release of dextran by the liver were greatly reduced by decreasing the temperature of the perfusion fluid to 8-10 C. These findings suggest that stasis in the hepatic circulation results in endocytotic uptake of perfusion fluid. A subsequent release of water increases the concentration of macromolecular substances inside the vacuoles. The decrease in the number of microvilli which occurred during stasis suggests that the membrane surfaces of these microvilli take part in the formation of endocytotic vacuoles.

3494 THE METABOLISM OF PHOSPHORIC ESTERS AND OF CYTIDINE-DIPHOSPHATE ESTERS OF CHOLINE AND ETHANOLAMINE IN THE LIVER. *(E.)* Binaglia, L.; Roberti, R.; Michal, G.; Porcellati, G. (Univ. Perugia, Italy). *Int. J. Biochem.* 4(24):597-611, 1973.

The labelled phosphate and cytidine-diphosphate esters of choline (CDP) and ethanolamine, together with their bases, were incubated with liver homogenate and microsomal membranes from female Wistar rats, and the transfer of radioactivity into water-soluble and lipid components examined. Very small amounts of phosphorylcholine are produced from choline *in vitro*; this contrasts with the considerable labelling *in vivo* of the liver phosphorylcholine from administered choline. Higher conversion of choline or phosphorylcholine is displayed by the microsomes supplemented by their supernatant, and this result points to the participation of these 2 fractions in the phosphorylating reaction. The conversion of phosphorylcholine to choline occurs in the microsomes to a considerable extent, and this points to the importance of this last fraction for the hydrolysis of soluble components. CDP-choline is strongly hydrolyzed back to phosphorylcholine, even in the absence of supernatant protein. Noticeable conversion of CDP-choline to lipid takes place. Choline is weakly converted into phosphorylcholine by either homogenate or microsomes, being almost totally recovered as intact molecules *in vitro* after 1 hour of incubation, and with slight conversion into betaine. Minimal but significant amounts of radioactivity are transferred into lipid material, and only trace amounts of CDP-choline are detectable. Phosphorylcholine is hydrolyzed back to choline by about 5% of the incubated amount after 1 hour. About 53% of CDP-choline is recovered as intact molecule in liver homogenate after 1 hour of incubation. The percentage of radioactivity of the incubated CDP-choline found in the free choline is of the order of 1.2 (homogenate) or 0.8 (microsomes). Very small conversion of ethanolamine to phosphorylethanolamine occurs in the liver homogenate and microsomes, smaller than that observed during conversion of choline to phosphorylcholine. Conversion of phosphorylethanolamine to ethanolamine takes place at a higher specific activity in the microsomal membranes as compared to homogenate. Lecithin is formed upon incubation with CDP-ethanolamine. Choline, phosphorylcholine, ethanolamine, and phosphorylethanolamine are barely utilized by liver preparations *in vitro*. Very small amounts of phospholipids are formed *in vitro* from these precursors, which in addition are recovered as intact molecules to a noticeable extent or transformed to a slight degree into other water-soluble components. Owing to the findings presented in this work, the question therefore arises whether choline and ethanolamine are the actual forms of metabolites which are utilized by the liver cell *in vivo* after their administration or whether they are quickly transformed into some more reactive molecules, which are successively transported to sites of utilization.

3495 HEPATIC MICROSOMAL MEMBRANE: ACTIVATION OF GLUCOSE-6-PHOSPHATASE. *(E.)* Carvo, M M.; Maddaiah, V. T.; Collipp, P. J.; Chen, S. Y. (Nassau Cty. Med. Ctr., East Meadow, N.Y.). *FEBS Lett.* 39(1):102-104, 1974.

The mechanism by which NH_4OH increases the activity of liver glucose-6-phosphatase *in vitro* was studied using lyophilized rat microsomes inactivated by pyr-idoxal-5'-phosphate (PLP). In microsomal preparations inactivated 8.5% by PLP, the percent activation by NH_4OH was 28. When percent inactivation by PLP was 40-50, the percent activation by NH_4OH was 36.6 to 52.7. Since the percent activation by NH_4OH was only 38.6 at 62% inactivation, some inactivation of unexposed or latent enzyme molecules may occur at higher PLP concentrations. Following treatment of the microsomal suspension with NH_4OH and subsequent centrifugation, about 90% of the enzymatic activity appeared in the supernatant; without NH_4OH treatment only 10% of the enzymatic activity appeared in the supernatant. The integrity of the microsomal membrane structure was retained after NH_4OH treatment. The data are consistent with the hypothesis that liver endoplasmic reticulum contains 2 kinds of glucose-6-phosphatase active sites. The readily accessible sites can be

ctivated by PLP, while NH_4OH can expose the
s accessible sites.

6 THE ROLE OF BILE SALTS IN THE HEPATIC EXCRETION OF IOPANOIC ACID.

(E.) Berk,
N.; Goldberger, L. E.; Loeb, P. M. (Univ. Cali-
nia, San Diego, Sch. Med., La Jolla). *Investi-*
ive Radiol. 9(1):7-15, 1974.

anoic acid excretion in the bile of dogs was
died during choleresis produced by B(2-4 di-
hoxy-5-cyclohexylbenzoyl) propionic acid (SC2644)
compound which stimulates bile-salt independent
alicular bile flow), sodium dehydrocholate (a
e-salt which increases bile-salt dependent bile
w but does not form micelles), and sodium tauro-
late (a micelle-forming bile salt choleretic).
eriments were performed in anesthetized and un-
sthetized dogs whose common ducts were catheter-
d immediately prior to the experiment, and in
anesthetized dogs prepared months earlier with a
mas cannula inserted into the duodenum. The
unt of iopanoic acid rose in proportion to the
rease in bile flow stimulated by dehydrocholate
taurocholate; the total excretion remained un-
nged by SC2644 choleresis. The failure of SC2644
increase the excretion of iopanoic acid despite
increase in bile flow indicates that the canali-
ar bile flow *per se* is not the important deter-
ant in regulating iopanoic acid excretion. Be-
se bile salts stimulated iopanoic acid excretion,
is the bile salts themselves and not the in-
ase in bile flow that influence iopanoic acid.
ce there was no difference in the effects of de-
rocholate and taurocholate, it is not the micellar
perty of the bile salts which enables these com-
nds to increase the rate of iopanoic acid excre-
n. There may be an allosteric interaction be-
en the bile salts and the carrier for iopanoic
d in the canalicular membrane which facilitates
transport of iopanoic acid from the hepatocyte
o the bile.

7 EFFECT OF SPIRONOLACTONE ON DRUG-METABOLIZING ENZYMES IN THE ENDOPLASMIC RETICULUM THE HUMAN AND RAT LIVER.

(Ger.) Leber, H. W.;
ders, P.; Schutterle, G. (Med. Clin., Univ.
ssen, Germany). *Verh. Dtsch. Ges. Inn. Med.*
1358-1362, 1972.

ce experimental studies have shown that large
es of spironolactone increase the rate at which
nopyrine is metabolized in rats by stimulating
ed-function oxidation in the liver, studies were
formed on human subjects with normal kidney and
er function to determine whether therapeutic
es of spironolactone have the same effect in man.
inistration of spironolactone (7 mg/kg/day p.o.)
7 subjects for 14 days before injection of metham-
one (1 g i.v.) caused no appreciable change in
nary excretion of 4-aminoantipyrine or N-acetyl-
minoantipyrine. The plasma half-life of aminopy-
e (12 mg/kg p.o.) in 10 subjects who had received
ronolactone (400-600 mg p.o. or i.v. for 2 weeks
more) was 3.86 ± 1.46 hr, while that determined
10 untreated controls was 3.94 ± 1.69 hr. This difference is not significant. These findings indicate that spironolactone does not increase the rate at which aminopyrine is metabolized in the human liver.

3498 EFFECT OF NICOTINAMIDE ON CARBOHYDRATE METABOLISM IN THE RAT LIVER DURING STARVATION.

(E.) Talke, H.; Maier, K. P.; Kersten, M.; Gerok, W. (Dept. Int. Med., Univ. Freiburg, Germany). *Eur. J. Clin. Invest.* 3(6):467-474, 1973.

A single high dose of nicotinamide (500 mg/kg) results in an 8-hr inhibition of lipolysis in adipose tissue by transformation to nicotinic acid. The effect of inhibited lipolysis on carbohydrate and amino acid metabolism after 48 hr starvation was examined in male Sprague-Dawley rats. Within 2 hr after i.p. injection of nicotinamide, the plasma level of free fatty acids (FFA) declines from 900 to 300 μval/l. The FFA level rises again between 8-12 hr after injection. The reduced supply of FFA to the liver leads to a reduced oxidation rate, characterized by a fall in the acetyl-nicotinamide content of the liver and of ketone bodies in liver and blood. Simultaneously there is an increase in protein catabolism. This increase is characterized by increased urinary excretion of urea up to 10 hr after nicotinamide injection and by a higher urea production rate in liver slices of rats pretreated with nicotinamide. In the liver the levels of the following amino acids rise very sharply: serine (100%), citrulline (400%), ornithine (250%), alanine (300%), aminobutyric acid (470%), valine (350%), leucine (250%), isoleucine (370%). The content of threonine is reduced to 63% and glycine to 50%. The levels of aspartic acid, glutamic acid, tyrosine, lysine, histidine, and arginine are unchanged. The result of the increased precursor supply for gluconeogenesis is a higher rate of glucose production, characterized by a 40 mg/100 ml increase in blood glucose, by an increase in liver glycogen content, by an increase in the concentrations of intermediates of the Embden-Meyerhof-pathway, mainly the concentrations of phosphoenolpyruvate (870%), 3-phosphoglycerate (480%), D-fructose 1,6-diphosphate (150%), D-glucose-6-phosphate (250%), and glucose (220%). In liver slice experiments the glucose production rate from L-alanine rises significantly after pretreatment of the animals with nicotinamide. The results show that a stimulation of gluconeogenesis is obtainable *in vivo*, although the oxidation rate is not a primary condition of stimulated gluconeogenesis.

3499 QUANTITATIVE ANALYSIS OF THE BILE ACID PATTERN IN SUBCELLULAR FRACTIONS OF THE LIVER.

(Ger.) Wildgrube, H. J.; Leuschner, U.; Al-Fureyh, A. (Ctr. Intern. Med., Univ. Frankfurt/Main, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78: 1395-1400, 1972.

Quantitative determinations were made of the bile acid content and pattern in mitochondrial, microsomal, and cytoplasmic fractions from livers of normal male Wistar rats which had been fasted for 12 hr. While the cytoplasm showed only traces of cholanic acid and the mitochondrial fraction accounted for only 1/16 of the bile acid present (6-60 μg/g mitochondria), the highest bile acid content was found in the microsomal fraction (30-1300 μg/g microsomes). The bile acid patterns differed in the microsomal and mitochondrial fractions, but these patterns varied greatly and no characteristic distribution was demonstrated for either fraction.

3500 CHOLESTEROL SOLUBILITY IN MODEL BILE SYSTEMS: IMPLICATIONS IN CHOLELITHIASIS.

(E.) Mufson, D.; Triyanond, K.; Zarembo, J. E.; Ravin, L. J. (Smith Kline, Franch Labs., Philadelphia, Pa.). *J. Pharm. Sci.* 63(3):327-332, 1974.

The solubility of cholesterol in a physiologically realistic model bile system was studied as a function of its (crystalline) form. Significant behavioral differences in the rate of solution and the approach to equilibrium were noted. The solubility of the equilibrium species, hydrated cholesterol, and of fresh human gallstones was approximately 5 mole/100 ml. Anhydrous and coprecipitated cholesterol samples attained metastable solubility values. The lag time for nucleation and growth in these systems could account for lab-to-lab variations found in previous studies and could be of extreme importance *in vivo* when lithogenic bile is present. Solubility was also measured as a function of the bile salt-lecithin ratio. Evaluation of the data with respect to available clinical data indicates that many normal individuals have bile which is supersaturated with cholesterol. Supersaturation is maintained until enough solute molecules are present to spontaneously aggregate into a stable cluster on which crystal growth can proceed, or until a suitable catalyst is added which triggers crystal growth.

3501 EFFECT OF ETHANOL ON LIPOPROTEIN METABOLISM IN THE ISOLATED PERFUSED RAT LIVER.

(Ger.) Garba, U.; Papenberg, J. (Med. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78: 1630-1631, 1972.

The effect of ethanol (43.5 mM) on lipoprotein synthesis and secretion was studied in isolated perfused livers from nonfasted rats. The quantity of apoprotein synthesized by 10 g liver over a 3-hr period was measured by determining the specific activity of apoprotein, in cpm/μg apoprotein, into which uniformly labeled ^{14}C-L-leucine had been incorporated. Ethanol inhibited secretion of very high density lipoproteins (VHDL) but had little effect on the secretion of low density and high density lipoproteins. This was surprising since ethanol induces secondary hyperpre-β-lipoproteinemia in man. This difference must result from differences in hepatic metabolism *in vivo* and *in vitro*. There were small differences in the specific activities of the various lipoprotein fractions which might be due to ethanol-induced changes in apoprotein composition.

3502 ASSESSMENT OF LIVER REGENERATION IN THE RAT USING THE GAMMA CAMERA.

(E.) Karran, S. J.; Leach, K. G.; Blumgart, L. H. (Welsh Natl. Sch. Med., Cardiff). *J. Nucl. Med.* 15(1):10-16, 1974.

A new method for imaging the liver and other organs of small animals makes use of a pinhole collimator and a gamma camera. Radioisotopic scintigraphs of the rat liver were obtained before and at various intervals after partial hepatectomy using ^{99m}Tc-sulfur colloid and ^{75}Se-L-selenomethionine. The scintigraphs of the two compounds were similar in size and there was no obvious difference in their distribution within the liver, either before or after partial hepatectomy. A close correlation was found between the mean area of the lateral scintigraphs of the liver and liver weight, and a formula was derived whereby liver weight could be calculated from the size of the scintigraphs. Following 2/3 partial hepatectomy in the rat, the remnant regained its normal mass within 7-10 days. The results show the usefulness of ^{99m}Tc-sulfur colloid in the clinical assessment of posthepatectomy liver regeneration.

3503 NITROGEN METABOLISM IN THE ISOLATED PERFUSED RAT LIVER. NITROGEN BALANCE, REDOX STATE AND RATES OF METABOLISM.

(E.) Parrilla, R.; Goodman, M. N. (Harvard Med. Sch., Boston, Mass.). *Biochem. J.* 138:341-348, 1974.

Nitrogen balances were measured in the isolated perfused livers of male Sprague-Dawley rats in the presence and absence of nitrogen donors. In all instances, the balance appeared to be incomplete. The expression (alanine)(α-oxogluarate)/(pyruvate)(glutamate) remained fairly constant under the metabolic conditions studied, indicating that it may have been at near equilibrium. The extra nitrogen appeared to be derived from increased hepatic proteolysis. The addition of a nitrogen donor to the perfusate arrested proteolysis, as did the addition of pyruvate. The free mitochondrial (NAD+)/(NADH) ratio, calculated from the glutamate dehydrogenase and β-hydroxybutyrate dehydrogenase reactants, showed similar values and exhibited parallel changes under most metabolic situations studied. The data indicate that under these conditions both dehydrogenases share a common mitochondrial NAD pool. Glutamate dehydrogenase appears to play an important role in hepatic nitrogen metabolism *in vivo*.

3504 FURTHER STUDIES ON THE TIME COURSE OF REREPRESSION OF TWO RAT LIVER ENZYMES.

(E.) Szepesi, B.; Slayton, C. A.; Michaelis, IV, O. E. (Nutrition Inst., Agr. Res. Serv., Beltsville, Md.). *Proc. Soc Exp. Biol. Med.* 145(2):729-733, 1974.

The activities of glucose 6-phosphate dehydrogenase (G6PD), 6-phosphogluconate dehydrogenase (6PGD), and malic enzyme (ME) were rerepresses following feeding of a high-fat diet to starving male specific pathogen-free Wistar rats. When such a regimen was followed, a second episode of starvation-refeeding no longer caused "increased inducibility" of these enzymes. Treatment of the rats with 8-azaguanine (0.5 ml i.p.) during feeding of the high-fat diet prevented the

fect of the diet on G6PD inducibility, decreased
e effect on ME inducibility, and had very little
fect on 6PGD inducibility. The results indicate
at transcriptional rerepression required exogenous
t and *de novo* RNA synthesis, but that 6PGD can be
repressed without *de novo* RNA synthesis. The data
rther indicate that the *de novo* RNA synthesis
cessary for the rerepression of G6PD and ME occurs
ring the second day of refeeding and coincides
th the time course of *de novo* RNA synthesis re-
irement for the enzyme overshoot.

05 THE EFFECT OF BILIARY OBSTRUCTION ON SOME PROPERTIES OF ALKALINE PHOSPHATASE OF RAT
VER. *(E.)* Moss, D. W.; Panov, E. Y.; Whitaker,
B. (Roy. Postgrad. Med. Sch., London, England).
in. Chim. Acta 51(1):41-46, 1974.

kaline phosphatase was significantly more heat
able in extracts from livers of rats with occluded
le ducts than enzyme extracted from normal liver.
is increased heat stability in bile duct-ligated rats
s maintained and even enhanced with prolonged
liary obstruction although total and specific ac-
vities of the enzyme decreased from the maximum
lues. The heat stability, expressed as the per-
ntage of activity remaining after incubation for
min at 56 C, was 51.65% 10 days after bile duct
gation compared with 45.99% after 24 hr. The
tio of orthophosphatase to inorganic pyrophosphate
tivity was also significantly higher in liver ex-
acts from bile duct-ligated rats than in normal
ver extracts. This ratio increased from 9.33 in
rmal liver to 18.04 24 hr after bile duct ligation
d 16.42 10 days after bile duct ligation. No
fferences were detected in the electrophoretic
bility or in Michaelis constants for orthophosphate
drolysis. Starch gel electrophoresis demonstrated
at the higher enzyme activity in bile duct-ligated
ts resulted from an increase in the activity of
e major, pre-existing anodic phosphatase fraction.
similar changes occur in the properties of
patic alkaline phosphatase in biliary obstruction
man, they may account for some of the observed
riations in the heat stability of serum alkaline
osphatase in patients with apparently similar di-
ases and total serum phosphatase activities.

06 INCREASED CARBON TETRACHLORIDE HEPATOTOXICITY, AND ITS MECHANISM, AFTER CHRONIC ETHANOL
NSUMPTION. *(E.)* Hasumura, Y.; Teschke, R.; Lieber,
S. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.).
stroenterology 66(3):415-422, 1974.

male Sprague-Dawley rats were pair fed a nutrition-
ly adequate liquid diet containing either ethanol
6% of total calories) or isocaloric carbohydrate
ontrols) for 4-5 weeks. Carbon tetrachloride (CCl_4)
s given intragastrically (0.5 ml/kg) 15 hr after
hanol withdrawal. In ethanol-fed rats, as compared
controls, significantly higher enzyme activities
re exhibited by serum ornithine carbamyl transferase
d glutamic pyruvic transaminase while the enzymes
patic aminopyrine N-demethylase and glucose-6-phos-
atase showed significantly lower activities. Con-
ntrations of liver lipid and serum bilirubin were
gnificantly higher but hepatic cytochrome P-450 content decreased significantly in the ethanol-treated rats. These findings indicate the *in vivo* potentiation of CCl_4 hepatotoxicity by chronic ethanol consumption, even in the absence of ethanol at the time of CCl_4 administration. For *in vitro* studies of the mechanism of ethanol-CCl_4 synergism, liver microsomes were incubated with CCl_4 and a reduced NADP-generating system. Results showed that CCl_4 destruction of cytochrome P-450 was much greater in microsomes of ethanol-treated rats. In addition, covalent binding of labeled CCl_4 metabolites to microsomal protein was increased and the enhancement of metabolism of $^{14}CCl_4$ to $^{14}CO_2$ in ethanol-fed rats was seen. Thus, it is suggested that the increase of CCl_4 hepatotoxicity in chronic ethanol fed rats is due to an enhanced microsomal activation and biotransformation of CCl_4.

3507 THE EFFECTS OF CERTAIN HYPOCHOLESTEROLEMIC AGENTS ON HEPATIC DELTA-AMINOLEVULINIC ACID SYNTHETASE LEVELS IN MICE.
(E.) Weissman, E. B.; Cheng, L. C.; Orten, J. M. (Buffalo Gen. Hosp., N.Y.). *Proc. Soc. Exp. Biol. Med.* 145(2): 438-441, 1974.

A study was made of the effects of *trans*-1,4-bis-(2 chlorobenzylaminomethyl)-cyclohexane dihydrochloride (3 mg/day for 3 days i.p.) and β-benzalbutyric acid (150 or 300 mg/kg/day for 4 days i.p.) on the activity of δ-aminolevulinic acid synthetase in the mitochondria of livers of white Swiss Webster mice injected with porphyrinogenic compounds. The porphyrinogenic agents were allylisopropylacetamide (6 mg s.c.) and 3,5-dicarbethoxy-1,4-dihydro-2,4,6-trimethylpyridine (6 mg s.c.). Both hypocholesterolemic agents prevented the usual induction of δ-aminolevulinic acid synthetase activity by porphyrinogenic agents. Administration of *trans*-1,4-bis-(2-chlorobenzylaminomethyl)-cyclohexane dihydrochloride also produced a consistent decrease (20%) in serum cholesterol levels. The data suggest that a decrease in the hepatic steroid pool and presumably that of 5β-H-steroid metabolites, as reflected by the serum cholesterol level, is associated with the observed decrease in hepatic mitochondrial δ-aminolevulinic acid synthetase. This study thus supports other evidence implicating steroid metabolites in the regulation of porphyrin-heme biosynthesis in a mammalian species.

3508 PROPERTIES OF RAT LIVER ALKALINE PHOSPHATASE BEFORE AND AFTER BILE DUCT LIGATION.
(E.) Righetti, A. B. B.; Kaplan, M. M. (New England Med. Ctr. Hosp., Boston, Mass.). *Proc. Soc. Exp. Biol. Med.* 145(2):726-728, 1974.

The properties of alkaline phosphatase were studied before and after "induction" by bile-duct ligation in male Charles River CD rats. Bile duct ligation caused a 5- to 10-fold increase in alkaline phosphatase activity. The enzyme in the bile duct-ligated rat liver was identical with the hepatic alkaline phosphatase from unoperated control rats in terms of electrophoretic mobility on polyacrylamide gel, rate of sedimentation in a sucrose gradient, rates of heat and urea denaturation, pH optima, and Michaelis constants. Since the 'induced' and base-level enzymes are identical by all criteria studied, it is unlikely that the increase in enzyme activity was due to activation of a preformed enzyme. Enzyme induction appears to be a more likely mechanism.

3509 EVIDENCE OF DEFECTIVE PROTEIN SYNTHESIS IN LIVER IN RATS WITH CONGENITAL HYPERBILIRUBINEMIA (GUNN). *(E.)* Majumdar, A. P. N.; Greenfield, S. (Inst. Med. Biochem., Univ. Aarhus, Denmark). *Biochim. Biophys. Acta* 335(2):260-263, 1974.

Liver slices from adult homozygous Gunn rats and normal rats were incubated with ^{14}C-leucine. The protein specific activity of all subcellular fractions prepared from Gunn liver homogenates was reduced by about 50% as compared with control values. In a second series of experiments, cell-free protein synthesis was studied using polyribosomes and dialyzed pH 5 enzyme fractions from homozygous and heterozygous Gunn and normal Wistar rat livers. Polyribosomes from homozygous rat livers incorporated 50% less ^{14}C-leucine than normal or heterozygous rat polyribosomes when incubated with homologous pH 5 enzyme fractions. In contrast, homozygous polyribosomes incubated with heterozygous or normal pH 5 enzyme fractions incorporated ^{14}C-leucine to the same extent as the other systems. Protein synthesis was also diminished in normal polyribosomes incubated with homozygous rat pH 5 enzyme fractions. The results indicated that the defect in protein synthesis in the adult homozygous Gunn rat is localized in the pH 5 enzyme fraction and not in the polyribosomes. The reduced *in vitro* protein synthesis in the homozygous Gunn rat is not due to higher ribonuclease activity in either the ribosomes or the pH 5 enzyme fraction. The data indicate bilirubin may be responsible for the lowering of protein synthesis in homozygous Gunn rats.

3510 EFFECTS ON CEREBRAL ENERGY STATE OF ARTERIAL HYPOTENSION IN RATS WITH PORTACAVAL ANASTOMOSIS. *(E.)* Holmin, T.; Johannsson, H.; Siesjo, B. K. (Univ. Hosp., Lund, Sweden). *Acta Physiol. Scand.* 90(2):345-357, 1974.

By bleeding the animals to mean arterial blood pressures of 45 and 30 mm Hg, the influence of arterial hypotension on the energy state of the brain was studied in male Wistar rats with end-to-side portacaval shunts. Reduction of blood pressure to 45 mm Hg in shunted rats produced no or only moderate accumulation of lactate, and there were no changes in the contents of ATP, ADP, and AMP in frontal lobe or brain stem. At a mean blood pressure of 30 mm Hg, shunted animals and controls showed similar values for glycolytic and citric acid cycle intermediates, amino acids, and adenine nucleotides in frontal lobe, parietal cortex, and brain stem. It is concluded that the portacaval shunt and the accompanying hyperammonemia did not adversely affect cerebral energy metabolism in any of the regions studied during hypotensive stress. Cerebral venous oxygen pressure was higher in shunted rats than in controls in these experiments. This finding is compatible with a decreased cerebral metabolic rate or with a relative increase in cerebral blood flow. Either factor may aid in protecting tissue against the metabolic effects of arterial hypotension.

3511 EFFECT OF DIETARY CHOLINE AND ETHANOL ON HEPATIC TRIGLYCERIDES AND ACTIVITY OF HEPATIC ETHANOL OXIDIZING ENZYMES IN RATS. *(E.)* Rifenbrick, D. H.; Narrod, S. A.; Myerson, R. M.; Scorpio, R. M. (Med. Coll. Pennsylvania, Philadelphia *Proc. Soc. Exp. Biol. Med.* 145(3):1061-1064, 1974.

Female CD rats were maintained for 21 days on a liquid diet with and without choline supplementation. Ethanol was given to half the rats as an isocaloric substitution for dietary sucrose. After 21 days, choline-deficient ethanol-fed rats had a mean liver triglyceride content significantly greater than that of choline-deficient controls. In contrast, choline-supplemented ethanol-fed rats had a mean liver triglyceride content not significantly different from choline-supplemented controls or rats fed laboratory chow. A significant increase in hepatic microsomal ethanol oxidizing system activity occurred only in choline-supplemented ethanol-fed rats. However, chronic ethanol administration did not increase hepatic alcohol dehydrogenase activity. The failure of microsomal ethanol oxidizing activity to increase in ethanol-fed choline-deficient rats could h resulted from a deficiency in phospholipid synthesis since increasing the choline content of the diet from 8 to 125 mg/100 ml resulted in significant stimulation. These results suggest that in rats choline not only protects against alcoholic fatty liver but also enhances stimulation of microsomal ethanol oxidizing activity induced by chronic ethanol feeding.

3512 MODERATE ETHANOL INGESTION AND PLASMA TRIGLYCERIDE LEVELS: A STUDY IN NORMAL AND HYPERTRIGLYCERIDEMIC PERSONS. *(E.)* Ginsberg, H.; Olefsky, J.; Farquhar, J. W.; Reaven, G. M. (Stanford Univ. Sch. Med., Calif.). *Ann. Intern. Med.* 80(2):143-149, 1974.

Plasma lipid, glucose, and insulin levels were measured in nonalcoholic normal subjects (4 men and 2 women; mean age, 28.5 yr) and hypertriglyceridemic subjects (6 men and 3 women; mean age, 44.8 yr) given moderate amounts of ethanol 3 times daily for 7 days. The subjects received 35 g ethanol with the noon meal, 35 g with dinner, and 17 g at bedtime. In the hypertriglyceridemic group, ethanol ingestion caused fasting plasma triglyceride levels to rise from a control value of 338 mg/100 ml to 498 mg/100 ml. There were no significant changes in the fasting plasma triglyceride levels of the 6 normal subjects. The postprandial triglyceride response to ethanol rose 37% in the normal group and 44% in the hypertriglyceridemic group. Fasting or postprandial glucose and insulin levels did not change during ethanol ingestion. The finding that moderate amount of alcohol can markedly exacerbate preexisting hypertriglyceridemia should be considered when treating patients with this disorder. Alcohol-induced hypertriglyceridemia can occur independently of any effect that alcohol might have on plasma glucose and insulin levels.

1 EFFECT OF HYPOPHYSECTOMY ON THE FUNCTION AND MORPHOLOGY OF THE SMALL INTESTINE MU-
A IN THE RAT. *(Ger.)* Menge, H.; Bloch, R.; Warm,
Lorenz-Meyer, H.; Riecken, E. O. (Med. Clin.,
v. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.*
1432-1434, 1972.

tological, morphometric, and histochemical exa-
ations were performed and, by means of an *in vivo*
fusion technique, glucose and glycine absorption
measured in the small intestine of 14 intact and
hypophysectomized rats. Of these 39 rats, 6 re-
ned untreated and, starting 4 weeks after surgery,
received substitution with growth hormone, 9 with
H, 6 with thyroxine, and 6 with gonadotropin for
eriod of 4 weeks. Examinations performed on un-
ated hypophysectomized rats 8 weeks after surgery
wed that the thickness of the wall of the small
estine was reduced, the lumen was narrowed, the
ght of the villi and depth of the crypts were
nificantly decreased, and the epithelium was
kedly flattened. A general reduction had occurred
epithelial enzyme activities, and values for glu-
e and glycine absorption were about 1/2 of those
nd in intact rats. A highly significant correla-
n was found between the height of the villi, on
one hand, and glucose and glycine absorption on
other. While growth hormone and thyroxine sub-
tution significantly increased body weight, the
ght of the villi, the depth of the crypts, and
cine absorption, these hormones caused only slight
reases in glucose absorption and had no effect on
of these parameters. These findings do not sug-
t that mucosal atrophy is compensated for by
ger epithelial cell lifetimes, as might be anti-
ated from the decrease which occurs in mitotic
ivity.

2 THE LACTASE-PHLORIZIN HYDROLASE COMPLEX IN THE HUMAN SMALL INTESTINE. *(Ger.)*
enz-Meyer, H.; Blum, A.; Semenza, G. (Biochem.
t., Federal Technical Coll., Zurich, Switzerland).
h. Dtsch. Ges. Inn. Med. 78:1413-1415, 1972.

orizin hydrolase, lactase, and sucrase were inves-
ated in homogenates of biopsies taken from the
er jejunum of 15 patients with no evidence of
trointestinal disease and of pieces of mucosa re-
ed from the jejunum of 2 other patients during
arotomy. The pH optimum of phlorizin hydrolase
pH 5, the K_m was 5 x 10^{-4}M, and almost all of
activity was precipitated when the homogenate
centrifuged at 150,000 g for 60 min, suggesting
t this enzyme is bound to membrane structures.
le no correlation was found between the activity
sucrase and that of phlorizin hydrolase, there
a significant correlation between lactase and
orizin hydrolase activities. The ratio of lac-
e to phlorizin hydrolase activity was 10:1. A
orizin hydrolase deficiency was observed in 4
ients with clinical evidence of a lactase defi-
ncy (abnormal lactose tolerance test). These
ymes differed significantly in the kinetics of
ir thermal inactivation, ruling out the possibili-
that lactase is responsible for hydrolyzing most
of the phlorizin. However, consideration of these data suggests that lactase accounts for 27% of phlorizin hydrolysis and has about 2.7% of the activity of phlorizin hydrolase. This is consistent with the finding that rat and hamster lactase can hydrolyze cellulose and many other β-glucosides. While native lactase in a homogenate of small intestine did cause slight competitive inhibition of phlorizin hydrolysis, this inhibitory effect was no longer evident after thermal denaturation of the homogenate. On the other hand, phlorizin caused significant competitive inhibition of lactose hydrolysis. These findings provide no evidence about whether one protein molecule or 2 molecules linked by noncovalent bonds is responsible for the activities of both enzymes.

3553 EFFECTS OF INTRADUODENAL ADMINISTRATION OF HCL AND GLUCOSE ON CIRCULATING IMMUNOREACTIVE SECRETIN AND INSULIN CONCENTRATIONS. *(E.)*
Boden, G.; Essa, N.; Owen, O. E.; Reichle, F. A.; Saraga, W. (Temple Univ. Health Sci. Ctr., Phila., Pa.). *J. Clin. Invest.* 53(4):1185-1193, 1974.

Portal and femoral venous dog blood samples were taken simultaneously before, during, and after intraduodenal infusion of HCl (21 mEQ/30 min) and glucose (131 ml/30 min). Mean portal venous immunoreactive secretin concentration of 6 dogs rose from 313 μU/ml before to 1060 μU/ml 10 min after initiation of the intestinal acidification. Femoral venous immunoreactive secretin concentration rose from 220 μU/ml before to 567 μU/ml 15 min after intestinal acidification. In the same 6 dogs, mean portal venous immunoreactive insulin concentration rose from 38 μM/ml before to 62 μU/ml at the end of the infusion. Pancreatic exocrine function was studied in 4 dogs. The rise in secretin concentration was followed by a highly significant increase in exocrine pancreatic flow rate and bicarbonate secretion. Glucose in concentrations from 2.5% to 10% had no detectable influence on portal or peripheral secretin concentration. Infusion of 50% glucose caused a slight decline in secretin concentration. The data indicate that immunoreactive secretin was released rapidly after intestinal acidification, continued to be secreted throughout the duration of HCl infusion, and was promptly distributed in the extracellular compartment. Endogenously released secretin apparently stimulates insulin secretion. The HCl-mediated insulinogenic effect of immunoreactive secretin, however, was too weak to influence peripheral immunoreactive insulin, glucose, and free fatty acid concentrations. The failure of intraduodenal glucose to stimulate secretin release suggests that secretin is not the insulin-stimulatory factory released from the gastrointestinal tract in response to oral glucose.

3554 THE ACTION OF SECRETIN AND PANCREOZYMIN ON SMALL-INTESTINAL ALKALINE PHOSPHATASE.
(E.) Warnes, T. W.; Hine, P.; Kay, G. (Manchester Roy. Infirm., England). *Gut* 15(1):39-47, 1974.

Secretin (1.7 Crick-Harper-Raper (CHR) U/kg) and pancreozymin (2.0 CHR U/kg) were administered i.v. to 16 normal humans, and the effects on the alkaline phosphatases of the bile, pancreas, and intestinal mucosa studied. Both hormones caused a significant rise in the output of alkaline phosphatase accompanied by a flow of bile and pancreatic juices into duodenal juice. There was no increase in sucrase or lactase in the duodenal juice. Pancreozymin caused a rise in bilirubin and pancreatic enzymes, while secretin caused a rise only in pancreatic enzymes. Secretin and pancreozymin also caused a rise in the output of alkaline phosphatase in 7 patients with complete obstruction to both the pancreatic and common bile ducts. In these patients, as well as in the normal subjects, the alkaline phosphatase was identified as intestinal in origin. Thus, both secretin and pancreozymin must cause small intestinal alkaline phosphatase to be released into the duodenal juice.

3555 THE EFFECT OF ASPIRIN ON DUODENAL SECRETION. *(E.)* Russell, T. R.; Jones, R. S. (Univ. California Sch. Med., San Francisco). *Proc. Soc. Exp. Biol. Med.* 145(3):967-969, 1974.

Volume secretions from duodenal pouches in mongrel dogs were measured before, during, and after aspirin administration (600 mg p.o. twice daily for 7 consecutive days). Aspirin was associated with a statistically significant decrease in duodenal secretory response to a meal. Before aspirin administration, duodenal secretion rose from 0.1 ml/15 min to a peak of 0.64 ml/15 min which occurred 1 hr after feeding. During aspirin administration, basal duodenal secretion was 0.04 ml/15 min and peaked at 0.27 ml/15 min during the sixth 15-min period following feeding. After aspirin was discontinued, duodenal secretion rose from a basal value of 0.02 ml/15 to a peak of 0.37 ml/15 min the fifth 15-min period after feeding; it subsequently declined to 0.1 ml/15 min at the end of the fourth hr after feeding. These results are due to the systemic effect of aspirin, as there was no direct contact of aspirin with duodenal mucosa.

3556 SOME OBSERVATION ON THE SMALL INTESTINAL OLIGOSACCHARIDASE ACTIVITIES IN NORMAL AND ALLOXAN DIABETES, BEFORE AND AFTER INSULIN THERAPY. *(E.)* Sharma, A. K.; Ghosh, A. K. (Coll. Med., Calcutta Univ., India). *Japan. J. Exp. Med.* 43(5): 443-446, 1973.

Studies on intestinal oligosaccharidase activity in normal and alloxan diabetes before and after insulin therapy were performed on albino rats. In alloxan diabetes, the activities of lactase, sucrase, and maltase were stimulated by 59.6%, 7.3%, and 31.4% respectively. After insulin therapy (2 units/100 g i.m. for 12 days) the lactase activity was reduced to 23.3% but sucrase and maltase activities were further stimulated by 40.5% and 37.8%, respectively. In normal rats after prolonged insulin therapy (2 units/100 g i.m. for 12 days), the lactase, sucrase, and maltase activities were stimulated by 41%, 46.6%, and 45.7%, respectively. The stimulation of lactase activity in alloxan diabetes was further proved by lactose absorption test in rabbits. There was much elevation of lactose absorption in alloxan diabetes, and after insulin therapy (5 units/kg of body weight) the lactose absorption was greatly reduced.

3557 METABOLISM OF TETRAHYDROCANNABINOL BY THE SMALL INTESTINE. *(E.)* Greene, M. L.; Saunders, D. R. (Dept. Med., Univ. Washington, Seattle). *Gastroenterology* 66(3):365-372, 1974.

The psychotomimetic effects of marihuana are probably due to hydroxylated metabolites of tetrahydrocannabinol (Δ^9THC), the major active alkaloid of the cannabis plant. Jejunal biopsies from normal volunteers were incubated in oxygenated flasks with purified ^{14}C-Δ^9THC (1.7 to 2.5 g/ml) in a nutrient medium. The activity of fresh biopsies was compared with that of control biopsies heated to 100 C for 3 min prior to their addition to the flask. After incubation and extraction, unchanged ^{14}C-Δ^9THC and its metabolites were chromatographically separated and quantified. In 6 experiments, an average of 5.4% of added ^{14}C-Δ^9THC was converted to polar metabolites in 2 hr. Metabolite formation was approximately linearly related to the duration of incubation and to tissue weight. The major (62%) polar metabolite of Δ^9THC formed by human jejunal mucosa had the chromatographic mobility of 11-hydroxy THC. To define the route whereby absorbed Δ^9THC and its metabolites leave the gut, ^{3}H-oleic acid and ^{14}C-Δ^9THC were fed intraduodenally to 2 rats equipped with thoracic duct fistulas. Over a period of 24 hr, 75% of the ^{3}H but only 1.3% of the ^{14}C were recovered in the lymph. The urine contained 12% of the administered ^{14}C. The portal absorption of ^{14}C-Δ^9THC was demonstrated in 4 intact rats: 30 min after feeding the labeled drug intraduodenally, the portal blood contained 3 to 4 times as much ^{14}C as did simultaneously sampled inferior vena caval blood. About half of the portal ^{14}C consisted of polar metabolites of Δ^9THC. Rat jejunal slices were also able to metabolize Δ^9THC. Thus, the human small intestinal mucosa is able to hydroxylate Δ^9THC. These cannabinoids are probably transported from the intestinal absorptive cells by the portal venous system.

3558 CALCIFEROL METABOLISM AND INTESTINAL CALCIUM TRANSPORT IN THE CHICK WITH REDUCED RENAL FUNCTION. *(E.)* Hartenbower, D. L.; Coburn, J. W.; Reddy, C. R.; Norman, A. W. (Wadsworth Hosp. Ctr., Los Angeles, Calif.). *J. Lab. Clin. Med.* 83(1):38-45, 1974.

The metabolism of ^{3}H- and ^{14}C-labeled cholecalcifero (vitamin D_3) and the intestinal transport of calcium, as measured *in vitro*, were evaluated in chicks with renal insufficiency of 7-10 days duration and in sham-operated control chicks. Previous treatment with nonradioactive D_3 was suboptimal, averaging 0.7-3.4 IU/day compared with normal requirements of 10-20 IU/day. Intestinal calcium transport was reduced in uremic chicks compared with control chicks. Also, there was reduced intestinal localization of labeled metabolite chromatographically identical to 1.25-dihydroxycholecalciferol (1,25(OH)$_2$D$_3$), the kidney-

oduced active form of D_3, in the uremic chicks
mpared with the sham-operated chicks. This dif-
rence was detectable only in the birds that re-
ived lower quantities of nonradioactive D_3. The
monstration of decreased quantities of $1,25(OH)_2D_3$
the intestine in association with impaired cal-
um transport are consistent with the theory that
duced availability of $1,25(OH)_2D_3$ may underlie the
normality of calcium absorption found in uremia.

59 ON THE DETERMINATION OF INTESTINAL EPITHELIAL CELL GENERATION TIME FROM LABELING
DEX AND DNA SYNTHESIS DURATION.

(E.) Cooper,
W.; Hagemann, R. F.; Brodmerkel, Jr., G. J. (Al-
gheny Gen. Hosp., Pittsburgh, Pa.). *Experientia*
(2):186-188, 1974.

le C57BL/J mice, some of which had been exposed
three X-ray treatments (300 r each), were injec-
d i.p. with 20 or 50 μCi of tritiated thymidine.
e labeling index was then determined in samples
jejunum, ascending colon, and descending colon.
addition, the labeling index was determined in
roral biopsy specimens of jejunum obtained from
patients and samples of ascending colon obtained
om 2 patients following surgery. Following ir-
diation, the jejunal generation cycle in the mur-
e samples was shortened (from 13.1 to 10.3 hr),
was the generation cycle in the ascending colon
rom 21.8 to 11.4 hr). For the mouse small intes-
ne and colon the relation Tg = Ts/LI (where Tg is
e generation time in hours, Ts is the duration
the S phase in hours, and LI represents the
action of labeled cells following a pulse expos-
e to tritiated thymidine) appears to be valid.
e labeling index in the proliferative zone of
man jejunal crypts averaged 34.5%, while the
beling index in the human colon averaged 40.6%,
elding a calculated generation time of 34.5 to
.2 hr. The potential errors in using Tg = Ts/
appear to result from the inclusion of goblet
lls and maturing columnar cells in the calcula-
ons.

60 TWO-TO-THREE DAY INTESTINAL PRESERVATION UTILIZING HYPOTHERMIC PULSATILE PERFUSION.

.) Toledo-Pereyra, L. H.; Simmons, R. L.; Najari-
, J. S. (Dept. Surg., Univ. Minnesota, Minneapolis).
n. Surg. 179(4):454-459, 1974.

e effects of hypothermic pulsatile perfusion with
bloodless perfusate on the survival of the canine
all bowel were studied, along with the functional
rameters of intestinal viability during storage.
nine small intestine was preserved by hypothermic
lsatile perfusion for periods up to 72 hr. During
e first 48 hr, there was a steady loss of perfu-
te into the bowel with a consequent organ weight
in. After 48 hr, the resistance of perfusion
se rapidly with consequent rises in perfusion pres-
re and falls in flow rate. The osmolarity of the
rfusate did not change significantly, although,
ter 48 hr, the sodium concentration fell slightly,
ile the potassium and lactic acid concentrations
se rapidly. There was a gradual and steady in-
ease in the LDH, SGOT, and B-glucuronidase concentrations of the perfusate. After 48 hr, d-xylose from the lumen rapidly entered the perfusate. The volume of intestinal secretions increased gradually during perfusion, as did the levels of total protein, globulin, sodium, and potassium. After 48 hr, acidosis, hypocapnia, and low oxygen consumption became increasingly severe as perfusate flow decreased and vascular resistance rose. Orthotopic intestinal allotransplantation was carried out in six intestines perfused for 72 hr. Immediately after revascularization there was gross evidence of serosal and mesenteric hemorrhage, with no microscopic evidence of mucosal damage. Intestinal transplantation was also carried out after 48 hr of perfusion in 14 dogs. Immediately after revascularization, there were signs of active tone and peristalisis with erythema of the serosa; biopsy revealed minimal interstitial inflammation.

3561 CHEMICAL AND HISTOCHEMICAL STUDIES OF POSTOPERATIVE SYMPATHETIC ACTIVITY IN THE DIGESTIVE TRACT IN RATS.

(E.) Dubois, A.; Kopin, I. J.; Pettigrew, K. D.; Jacobowitz, D. M. (Natl. Cancer Inst., Bethesda, Md.). *Gastroenterology* 66(3):403-407, 1974.

In the rat, the postoperative inhibition of gastrointestinal propulsion is accompanied by the increased synthesis of norepinephrine from ^{14}C-tyrosine. Endogenous stores of norepinephrine are not significantly modified. The peripheral sympathetic response to abdominal surgery was further examined by blocking norepinephrine synthesis in male albino rats with α-methyl-p-tyrosine (αMPT). The rate of decline of tissue norepinephrine stores was taken as an index of local adrenergic activity. Twelve hr after intestinal exteriorization, the αMPT-induced decrease in digestive tract norepinephrine was more profound than in unoperated rats. This difference was not observed in the heart. Histofluorescence studies showed that neither surgery nor αMPT treatment modified the distribution of norepinephrine in the gut wall. In operated αMPT-treated animals, there was a dramatic decrease in fluorescent intensity in the noradrenergic nerves of the Auerbach plexus, the Meissner plexus, and the circular muscle. The intensity of fluorescence in the perivascular adrenergic nerves was unaltered. The difference between the perivascular and the myenteric plexus in relation to the depletion of norepinephrine by αMPT is probably due to a more rapid turnover of the catecholamine in the plexus. Intestinal manipulations thus appear to increase both the synthesis and release of norepinephrine from noradrenergic nerves in the gut wall. This local hyperactivity of the sympathetic nerves could account for the postoperative ileus observed in man.

3562 ANTAGONISM OF METHADONE'S INTESTINAL EFFECTS BY CYPROHEPTADINE.

(E.) Kennedy, D. K.; Grubb, M. N.; Burks, T. F. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 66(3):396-402, 1974.

The narcotic agonist methadone increases the amplitude of intestinal phasic contractions and can retard intestinal propulsive activity. Like morphine, methadone may produce its intestinal effects *via* the release of local 5-hydroxytryptamine (5-HT). The ability of the 5-HT receptor blocking agent cyproheptadine to antagonize the intestinal effects of methadone was evaluated *in vitro* and *in vivo*. In vascularly perfused segments of isolated canine intestine, cyproheptadine (1 μg/ml) decreased the stimulatory effect of methadone and 5-HT, but not the effect produced by bethanechol, a cholinergic agonist. Atropine decreased the responses to methadone, 5-HT, and bethanechol because one component of 5-HT action is mediated by intramural cholinergic nerves. Cyproheptadine also antagonized the methadone-induced reduction in transit of test meals in mice. The LD_{50} of methadone (28.3 mg/kg) was not altered by cyproheptadine (10 mg/kg). The ability of a 5-HT blocking agent to antagonize the intestinal effects of methadone suggests a potentially useful means of overcoming one of the troublesome side effects of the narcotic drugs.

3563 STUDY OF PANETH CELL SECRETION USING LYSOZYME AS A MARKER. *(E.)* Peeters, T.; Vantrappen, G. (Dept. Med. Res., Univ. Louvain, Belgium). *Gastroenterology* 66(4):758, 1974.

3564 ABSENCE OF SIGNIFICANT RATES OF GLUCONEOGENESIS IN INTESTINAL MUCOSA OF STARVED GUINEA PIGS. *(E.)* Lamers, J. M. J.; Kurpershoek-Davidov, R.; Hulsmann, W. C. (Fac. Med., Erasmus Univ., Rotterdam, Netherlands). *Biochim. Biophys. Acta* 343(2):427-430, 1974.

GENERAL

3570 PREDICTION OF THE VIABILITY OF REVASCULARIZED INTESTINE WITH RADIOACTIVE MICROSPHERES. *(E.)* Zarins, C. K.; Skinner, D. B.; Rhodes, B. A.; James, Jr., A. E. (Dept. Surg., Univ. Michigan, Ann Arbor). *Surg. Gynecol. Obstet.* 138(4):576-580, 1974.

Vascular supply to the terminal portion of the ileum was occluded in 16 adult beagle dogs. After an ischemic period of 4-10 hr, the segment was revascularized. After periods of 10 min, 4 days, and 1 month, radionuclide-labeled microspheres were injected into the aortic blood stream to assess microcirculatory blood flow. Of 14 scintiscans performed 10 min after revascularization, 5 were hyperemic, 4 were normal, and 5 were ischemic. All 5 dogs with hyperemic scintiscans had viable intestines with normal color and vascular pulsations after revascularization. All 4 dogs with normal scintiscans had grossly normal viable intestines, but 1 dog died of intestinal infarction after 4 days and another was moribund and had cachexia after 1 month due to stricture of the ischemic segment. Among the 5 dogs with ischemic scintiscans, 3 intestinal segments appeared grossly viable and two appeared necrotic after revascularization; none proved to be viable. As the duration of ischemia progressed, the hyperemic response diminished. Follow-up observation scintiscans at 4 days and 1 month showed the persistence of hyperemia in previously ischemic intestinal segments: hyperemia detected at these times correlated with injured tissue. The data indicate that hyperemia or ischemia as seen by scintiscanning immediately after revascularization was a useful prognostic indicator of viability, while normal scintiscans were of indeterminate predictive value. Clinical evaluation of this technique seems warranted.

3571 EXPERIMENTAL SHIGELLOSIS AND INTESTINAL MALABSORPTION IN THE MOUSE. *(E.)* Madge, D. S. (Dept. Biol. Sci., Wye Coll., Ashford, Kent, England). *Comp. Biochem. Physiol.* 48A(2):343-359, 1974.

Inbred CS-1 mice were inoculated p.o. with suspen-

ions of human strains of *Shigella dysenteriae* and
flexneri, then injected i.p. with morphine sul-
ate to reduce intestinal peristalsis. After 1
eek, the infected animals showed decreased *in vitro*
ntestinal absorption of D-glucose, D-galactose,
-histidine, or L-arginine. Serosal fluid transfer
nd tissue fluid uptake were generally reduced. The
ffects of the infection disappeared after 2 weeks.
he absorption of D-glucose was decreased throughout
he small intestine. Intestinal fluid transfer
ell in the duodenum, jejunum, and proximal ileum,
ut rose in the distal ileum. The amounts of food
nd water taken by the infected mice did not change.
ody weight, as well as fresh weight and protein
ontent of the small intestine, also remained unal-
ered. The histology of the mucose changed mainly
istally. There is a glucose-dependent and glucose-
ndependent fluid transfer mechanism in the normal
ouse small intestine: the first is more important
roximally and the second is more important distally.
n animals with shigellosis, both mechanisms re-
ained unchanged in the proximal and mid-intestine
ut increased in the distal intestine. Thus, total
luid transfer in the infected intestine increased
rogressively along the intestine, unlike the nor-
l intestine where it is highest in the mid-intes-
ine and decreases proximally and distally.

72 ROLE OF THE INTRAINTESTINAL GRAM-NEGATIVE BACTERIAL FLORA IN RESPONSE TO MAJOR INJURY.
.) Hamer-Hodges, D.; Woodruff, P.; Cuevas, P.;
ufman, A.; Fine, J. (Boston City Hosp., Mass.).
rg. Gynecol. Obstet. 138(4):599-603, 1974.

series of adult white New Zealand rabbits harboring
nventional aerobic gram-negative basteria were
bjected to a lethal dose of i.v. administered
dotoxin, occlusion of the superior mesenteric
tery for 1 hr, and a 30% immersion burn. All of
ese injuries produced fatal endotoxic shock within
hr. The same injuries were inflicted on another
ries of rabbits which were comparable in all
spects except that the aerobic gram-negative bac-
ria were either absent or present in small numbers
the cecum, the bacterial count in the cecum being
low 10^5 instead of 10^9 or 10^{10} and the endotoxin
ter being below 0.125 mg as compared with 6 mg/g
cecal content. Endotoxemia of intestinal origin
veloped in the first series shortly after the in-
ry was inflicted and caused fatal shock within 12
. None of the animals in the second series de-
loped endotoxemia or shock, and some were alive
d well 24 hr later. However, in rabbits in which
e intestines were preloaded with gram-negative
ora in a fluid containing nutrients shortly before
jury, endotoxemia did develop and the mortality
te was substantially greater. Thus, the intrain-
stinal gram-negative flora and their endotoxins
pear to be the source of additional injury which
n account for the shock and death which follow
rious types of major trauma.

73 EFFECT OF A TOPICAL ADRENERGIC AGENT ON GASTRIC BLOOD FLOW. *(E.)* Waterman, N.
; Walker, J. L. (Univ. Louisville Sch. Med., Ky.).
. J. Surg. 127(3):241-243, 1974.

Irrigation of the stomach with saline containing levarterenol (16 mg/liter) had only a small additive effect on the reduction of gastric blood flow in dogs, regardless of the temperature of the saline. Gastric irrigation with saline at 38 C decreased blood flow by 10%, while irrigation with iced saline decreased it by 50%. Addition of levarterenol to saline at 38 C or at 6-8 C further decreased blood flow by 8 and 10%, resp., between 15 and 30 min after initiation of the irrigation. Since gastric cooling can adversely affect hemostatic mechanisms, a controlled clinical study is needed to determine the effectiveness of the various methods of gastric irrigation in the treatment of upper gastrointestinal bleeding.

3574 PROLONGED SURVIVAL OF CANINE ORTHOTOPIC SMALL INTESTINAL ALLOGRAFTS PRESERVED FOR 24 HOURS BY HYPOTHERMIC BLOODLESS PERFUSION. *(E.)* Toledo-Pareyra, L. H.; Simmons, R. L.; Najarian, J. S. (Dept. Surg., Univ. Minnesota, Minneapolis). *Surgery* 75(3):368-376, 1974.

Whole orthotopic small intestinal transplants were carried out in moderately immunosuppressed dogs. Survival times were compared for dogs with fresh grafts and those with grafts preserved by hypothermic bloodless pulsatile perfusion for 24 hr. Two perfusates were used during preservation: cryoprecipitated pooled dog plasma or human plasmanate. Survival was significantly better in the dogs which received the preserved grafts than in animals with fresh transplants (mean survival, 14.5 days). The best survival time was achieved with intestinal allografts perfused with human plasmanate (mean survival, 45 days; the longest, 67 days). These results suggest that significant prolongation of allograft survival in moderately immunosuppressed animals might be achieved by modification of graft immunogenicity upon preservation or by binding with nonspecific xenogeneic antibodies in a perfusate solution. Except for differences in survival, there were practically no clinical differences among the 3 groups of dogs. All animals lost weight at almost the same weight, and weight loss reached 30% in dogs which survived more than 6 weeks after grafting. Anemia and hypoproteinemia with hypoalbuminemia were constant features in all dogs and preoperative values were not attained in any animal, although slight improvement in serum protein and albumin levels were observed 5 weeks after transplantation in the human plasmanate group.

3575 POLYSACCHARIDES IN HUMAN GALLBLADDER WALL AND BILE. *(E.)* Terho, T.; Laitio, M. (Dept. Physiol., Univ. Turku, Finland). *Biochim. Biophys. Acta* 338(1):135-150, 1974.

Polysaccharides in human gallbladder wall and bile were isolated and characterized. In the gallbladder wall hyaluronic acid, heparin sulfate, dermatan sulfate and chondroitin 4- and/or 6-sulfate were found. Most hyaluronic acid and chondroitin 4- and/or 6-sulfate proteoglycan were extractable with 0.9% NaCl from the gallbladder wall, whereas dermatan sulfate proteoglycan was almost insoluble in 0.9% NaCl. In bile, hyaluronic acid and chondroitin 4- and/or 6-sulfate were found only in trace amounts. Both from the gallbladder wall and from bile, 2 large molecular polysaccharides were isolated, which were assumed to be the polysaccharide parts of so-called mucins. The polysaccharides were composed of glucosamine, galactosamine, and galactose (in the ratio of 3:1:4 or 9:1:10) and of different amounts of fucose, sialic acid, and sulfate. The polysaccharides were fractionated further according to their sialic acid and sulfate content. In addition, large amounts of small molecular polysaccharides were isolated from the gallbladder wall and bile. These polysaccharides consisted of varying amounts of glucosamine, galactose, glucose, mannose, fucose, and sialic acids. In the gallbladder wall these polysaccharides (at the glycoprotein stage) were both soluble and insoluble in 0.9% NaCl. The insoluble polysaccharides were assumed to originate from structural or membrane-bound glycoproteins, e.g., plasma membrane glycoproteins.

3576 EFFECT OF ETHANOL ON THE TRANSPORT OF NUCLEOSIDES INTO PRIMARY CHICK FIBROBLASTS.

(E.) Scholtissek, C. (Inst. Virol., Justus Liebig-Univ., Giessen, Germany). *Biochim. Biophys. Acta* 335(3):290-294, 1974.

In primary tissue cultures prepared from 11-day-old chick embryos in Petri dishes, the uptake of labeled uridine is considerably inhibited by ethanol in a dose-response relationship. To reduce the uptake of guanosine to a comparable level an approximately 2-fold higher concentration of ethanol has to be employed. In the case of adenosine the concentration of ethanol is even 5 times as high. Since the inhibition of the incorporation of labeled uridine into RNA parallels the inhibition of the uptake into the acid-soluble pool, a direct interference with RNA synthesis does not seem to occur. The incorporation of $[^3H]$UTP prelabeled at 4 C *in vivo* into RNA is not significantly influenced by ethanol during the first 30 min of incubation at 37 C. The incorporation of labeled leucine and the multiplication of fowl plague virus are also severely inhibited by ethanol. All these effects are reversible. When ethanol is added to the cultures at concentrations higher than 10%, the cell layers show microscopically visible cytotoxic effects. In the presence of 9% ethanol, prelabeled UTP is lost from the cells during incubation at 37 C. Incubation with 9% ethanol for 90 min has only a little effect on the ATP pool. The effect on the GTP pool is negligible. Ethanol at concentrations of 6% and above has a significant depressive effect on the uridine kinase (30% depression by 6% and 50% depression by 9% ethanol). However, the rather drastic effect of ethanol even at low concentrations on the uptake of uridine cannot be merely explained by its influence on the pyrimidine nucleoside kinase activity.

3577 SEQUENCE OF EVENTS MEDIATING THE EFFECT OF CHOLERA TOXIN ON RAT THYMOCYTES. *(E.)*

Boyle, J. M.; Gardner, J. D. (Natl. Inst. Hlth., Bethesda, Md.). *J. Clin. Invest.* 53(4):1149-1158, 1974.

In rat thymocytes, binding of (^{125}I)choleragen was followed by cellular accumulation of cyclic 3',5'-AMP which, in turn, was followed by stimulation of amino acid transport. Binding of cholera toxin was complete by 30 min and remained constant for the subsequent 150 min. After stimulation by choleragen, cellular cyclic 3',5'-AMP became maximal by 30 min, after which it declined steadily so that by 90 min of incubation, cellular cyclic nucleotide levels were only 20% of those seen at 30 min. Stimulation of amino acid transport, although detectable by 15 min, did not become maximal until 120 min (by which time cellular cyclic 3',5'-AMP had decreased by more than 80%). This system was also used to delineate the step at which various pharmacologic agents and hormones act to alter the sequence of events mediating the response of rat thymocytes to cholera toxin. The ability of cycloheximide to abolish choleragen-stimulated amino acid influx without reducing (^{125}I)-choleragen binding or cellular cyclic 3',5'-AMP suggests that cyclic nucleotide stimulation of amino acid transport includes a step involving protein synthesis.

3578 SYNERGISM BETWEEN ECOLOGIC AND IMMUNOLOGIC CONTROL MECHANISMS OF INTESTINAL FLORA.

(E.) Shedlofsky, S.; Freter, R. (Dept. Microbiol., Univ. Michigan, Ann Arbor). *J. Infect. Dis.* 129(3):296-303, 1974.

A hypothesis postulating that local antibacterial immunity may act synergistically with bacterial antagonism in controlling bacterial populations in the intestine was studied. In germ-free Charles River mice monoassociated with *Vibrio cholerae*, bacterial counts were in the order of 10^9 to 10^{10} bacteria/cecu If mice had been vaccinated with *V. cholerae* by either p.o. or parenteral routes, the vibrio counts were lowered by factors of only 1.55-2.82. In germ-free mice in which antagonistic bacteria had been implanted before challenge with vibrios, viable counts were about 10^5 to 10^8 vibrios/cecum. If these mice were vaccinated, the vibrio counts were lowered by factors of 4.72 to 61.1. Local antibacterial immunity was therefore considerably more effective when it operated in conjunction with bacterial antagonism. The most important function of local antibacterial immunity appears to be protection against invading bacteria, including pathogens such as *V. cholerae* and *Escherichia coli*. However, local immunity appears to function only if the initial populations of these invaders are kept small by such mechanisms as peristalsis in the small intestine or the antagonistic action of a properly functioning normal flora in the mouth, throat, or large intestine

3579 SIMILARITIES BETWEEN ONE OF THE MULTIPLE FORMS OF PEPTIDE HYDROLASE PURIFIED FROM BRUSH-BORDER AND CYTOSOL FRACTIONS OF GUINEA PIG INTESTINAL MUCOSA.

(E.) O'Cuinn, G.; Donlon, J.; Fottrell, P. F. (Dept. Biochem., Univ. Coll., Galway, Ireland). *FEBS Lett.* 39(2):225-228, 1974.

In guinea pigs, properties of one of the forms of peptide hydrolase isolated from the cytosol of the enterocytes were compared with an

yme of similar electrophoretic mobility,
ified from brush-border fractions. When aliquots
the purified brush border α peptide hydrolase were
ubated with equal volumes of various dilutions of
i-cytosol α peptide hydrolase antibody, the re-
tant complex was precipitated by centrifugation
30,000 g for 15 min. When a γ globulin prepara-
n from control rabbit serum was substituted for
antiserum, the peptide hydrolase activity was
precipitated but remained in the supernatant af-
centrifugation. When cytosol and brush border
yme preparations were preincubated with antiserum
control serum and the mixtures run on starch-gel
ctrophoresis, the resultant zymograms indicated
t the antiserum reacted only with the α peptide
rolase of both brush-borders and cytosol. Thir-
n dipeptides and 4 tripeptides were used to compare
substrate specificities of the cytosol and brush
der enzymes. Both enzymes hydrolysed the same
strates and had no effect on peptides containing
line or acidic amino acid residues with the ex-
tion of L-Glu-L-Tyr. Various divalent cations
e tested for their ability to stimulate hydrolysis
L-Leu-L-Leu by the brush-border hydrolase. Both
ganese (0.5 mM) and magnesium (0.5 mM) promoted
rolysis, the managanese ion being more efficient.
c and cobalt inhibited hydrolysis while calcium
the same concentration (0.5 mM) had little effect.
is concluded that at least one of the multiple
ms of peptide hydrolase i.e., α peptide hydrolase
very similar properties when isolated from either
cytosol or brush-border fractions of guinea-pig
estinal mucosa.

0 HEMODYNAMIC OBSERVATIONS OF ADYNAMIC ILEUS
IN THE CONSCIOUS DOG. *(E.)* Abe, H.; Ap-
t, H. E.; Howard, J. M. (Hahnemann Med. Coll.,
la., Pa.). *Ann. Surg.* 179(3):332-338, 1974.

emodynamic study on mongrel dogs was performed in
course of acute peritonitis due to appendiceal
ation. Adynamic ileus developed approximately
r after the procedure. The mechanical activity
the ileum was greatly reduced within the first 6
and was associated with a similar reduction in
number of spike potentials which could be ob-
ved. Slow wave electrical activity, however, was
tained and was relatively unchanged in rate and
litude until the time of death. Intestinal motili-
and splanchnic hemodynamics appeared to undergo
tages of deterioration. An initial response to
ury, a stage of inflammation, a stage of adynamic
us, and a stage of peripheral vascular collapse
ld be distinguished. The superior mesenteric ar-
y flow and resistance returned to approximately
trol values during the stage of ileus. In the
ly stage of vascular collapse, flow began to de-
ase and the resistance was increased. It is pro-
ed that these hemodynamic changes are related
e to the humoral factors than to simple splanchnic
ve stimulation.

1 INFLUENCES OF DIETARY AND ENVIRONMENTAL
STRESS ON MICROBIAL POPULATIONS IN THE
INE GASTROINTESTINAL TRACT. *(E.)* Tannock, G. W.; Savage, D. C. (Dept. Microbiol., Univ. Illinois, Urbana). *Infect. Immun.* 9(3):591-598, 1974.

Aerobic and anaerobic cultural techniques and histological methods were used in a study of the effects of environmental and dietary stress on the indigenous microbiota of the gastrointestinal tract of mice. Mice previously inoculated with *Salmonella typhimurium* were examined in a similar manner. Three strains of mice (CD-1, Ha/ICr, and C57BL) were used. Control animals previously inoculated with *S. typhimurium* had low population levels of *Salmonella* bacteria in the small and large bowel. Mice previously inoculated with *Salmonella* and then deprived of food, water, and bedding for 48 hr harbored high population levels of these bacteria in their small and large bowels. Coliforms increased in numbers in the large bowel of stressed mice inoculated with *Salmonella* and in the jejunum-ileum and cecum of stressed mice not previously inoculated. Control mice had high population levels of lactobacilli inhabiting the keratinized squamous epithelium of the stomach. Stressed mice showed dramatic reductions in these populations of lactobacilli. Populations of fusiform-shaped bacteria associated with the mucosal epithelium of the cecum and colon in control mice were reduced in stressed mice as determined by microscope examination of histological sections. Total anaerobic counts were similar, however, in both stressed and control animals. Environmental and dietary stress markedly alter the gastrointestinal microbiota in mice. Therefore, such stressful conditions profoundly affect the factors that regulate the localization and population levels of microorganisms in the stomach and intestines.

DIAGNOSTIC PROCEDURES

3611 ENDOSCOPIC PANCREATOCHOLANGIOGRAPHY WITH SPECIAL REFERENCE TO MANOMETRIC METHOD.

(E.) Kasugai, T.; Kuno, N.; Kizu, M. (Aichi Cancer Ctr., Nagoya, Japan). *Med. J. Aust.* 2(15):717-725, 1973.

Of 496 patient endoscopic examinations, 451 (90.9%) cannulations were successfully performed, resulting in 251 endoscopic pancreatograms (EPG), 152 endoscopic pancreatocholangiograms (EPCG), and 48 endoscopic cholangiograms (ECG). The selected ducts were visualized in 83.3% of attempted cases. A manometer was developed to measure and control the injecting pressure of the contrast medium in EPCG. The total volume of injecting dye was 15-22 ml for EPCG, 10-20 ml for EPG, and over 15 ml for ECT. Eight cases of carcinoma of the head of the pancreas and 10 cases of pancreatic carcinoma located in the body and/or tail were diagnosed by EPCG. Chronic pancreatitis was classified into 3 groups: minimal, moderate, and advanced, according to a grading of findings in EPCG. In 157 cases of chronic pancreatitis, 68 showed minimal, 60 moderate, and 29 advanced stage of chronic pancreatitis. The criteria for EPCG diagnosis of chronic pancreatitis were evaluated by the study of postmortem pancreatograms and by histological investigation. A correlation between results for both investigations was demonstrated in 79% of normal findings and in all cases of chronic pancreatitis. Various diseases of the biliary systems were successfully confirmed by EPCG. This group included 3 cases of carcinoma of the gallbladder, 6 of carcinoma of the bile duct, some metastic liver tumors, and a liver abscess. It appears that EPCG is one of the most reliable procedures to detect diseases of the pancreatic and biliary systems, especially space-occupying lesions and also chronic inflammatory changes in the pancreas.

3612 THE DIAGNOSIS OF HEMOBILIA BY PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY. *(E.)*

Myers, R. N.; Haupt, G. J.; Birkhead, N. C. (Lankenau Hosp., Philadelphia, Pa.). *Am. J. Gastroenterol.* 60(5):510-512, 1973.

A case report is presented of a 26-yr-old man with traumatic hemobilia, correctly diagnosed preoperatively by percutaneous transhepatic cholangiography. This roentgenographic study showed numerous filling defects in the biliary ductal system and gallbladder which were interpreted as blood clots. There was also extravasation of dye from the biliary tree into an area of damaged liver parenchyma. These findings were confirmed at operation and a right hepatic lobectomy performed to resect all damaged hepatic tissue and control bleeding. The patient's recovery was uneventful. The technique for percutaneous cholangiography utilizes a lateral intercostal approach, with flexible Teflon tubing, gravity drainage of bile, and cinefluorographic monitoring and filming. Both roentgenograms and cinefluorograms were taken during filling of the biliary system and gallbladder with dye (50% sodium diatrizoate).

3613 SERIAL CARCINOEMBRYONIC ANTIGEN ASSAYS: USE IN DETECTION OF CANCER-RECURRENCE.

(E.) Sorokin, J. J.; Sugarbaker, P. H.; Zamcheck, N.; Pisick, M.; Kupchik, H. Z.; Moore, F. D. (Harvard Med. Sch., Boston, Mass.). *JAMA* 228(1):49-53, 1974.

A prospective study of 102 patients who had undergone potentially curative operations for colorectal cancer was undertaken to correlate serial carcinoembryonic antigen levels with the clinical course. When included in this study, patients selected had no detectable metastatic or recurrent disease. Twelve patients developed sustained elevations in their carcinoembryonic antigen levels greater than 2.5 ng/ml. Six of these had progressively rising carcinoembryonic antigen titers, and all developed subsequently recurrent cancer; rising carcinoembryonic antigen levels were observed up to 29 months before cancer recurrence was clinically detected. The 6 with "stable" elevations and 6 with transient elevations developed no clinically detectable cancer. Eighty-four patients with carcinoembryonic antigen levels consistently under 2.5 ng/ml had no evidence of recurrent neoplasms. Two developed second primaries. Serial carcinoembryonic assays postoperatively help detect recurrent colon cancer in asymptomatic patients.

3614 PAEDIATRIC OESOPHAGEAL MANOMETRY. *(E.)*

Chappell, J. S.; Bremner, C. G. (Baragwanath Hosp., Johannesburg, South Africa). *S. Afr. Med. J.* 40(3):1875-1877, 1974.

The lower esophageal sphincter was studied manometrically in 18 babies aged 1 day to 9 months. Ten babies were normal and 8 had feeding problems with vomiting and regurgitation. The lower esophageal sphincter in newborns was 0.5-1 cm in length; in all babies it was placed at or below the effective diaphragmatic hiatus at rest. The mean sphincter pressure in normal babies was 8 mm Hg and the mean fundo-esophageal gradient was 9 mm Hg. In 3 abnormal babie the mean sphincter pressure was 5 mm Hg and the mean fundo-esophageal gradient was 7 mm Hg. Of these grou 1 had a hiatus hernia, 1 a definite chalasia, and 1 intermittent vomiting. The remaining 5 abnormal babies had a mean sphincter pressure of 18 mm Hg and a mean fundo-esophageal gradient of 11 mm Hg. This group included 1 patient with hypertrophic pyloric stenosis, 1 with cerebral palsy with pharyngeal and esophageal incoordination, and 3 persistent vomiters. The results indicate the value of pressure tracings of the lower esophagus in the evaluation of patients with persistent vomiting of a functional nature.

3615 ENDOSCOPIC DIAGNOSIS OF PRIMARY CARCINOMA OF THE SMALL INTESTINE. *(E.)*

Seifert, E.; Wagner, H. H.; Reichel, K.; Braschke, M.; Ostertag, H. (Med. Coll., Hannover, Germany). *Am. J. Gastroenterol.* 61(1):15-21, 1974.

In a male patient, aged 47, who presented with melena of 8 months' duration and of uncertain origin, x-ray examination suggested a malignant tumor with fistulas at the duodenojejunal flexure. Duodenoscopy with a fiberoptic system and selective biopsy established the diagnosis of an adenocarcinoma pri-

to surgery. In the case of a man, aged 62, who
l complained of nonspecific pains in the epigas-
ium for 2.5 yr and presented with severe anemia
r 3 months, duodenoscopy with a fiberoptic system
l biopsy, carried out because a lesion was sus-
cted on x-ray examination, demonstrated an adeno-
rcinoma in the *pars horizontalis* inferior of the
odenum. Radical surgery was possible in both
ses. In each, the indication for surgery was
finitely given by preoperative endoscopy and biopsy
ndings. It is concluded that duodenoscopy with
lective biopsy is the surest method of diagnosing
mors of the small intestine.

6 ANGIOGRAPHIC DIAGNOSIS OF LEIOMYOMATOUS
SMALL BOWEL TUMORS. *(E.)* Itzchak, Y.;
ar, R.; Mozes, M.; Deutsch, V. (Tel-Aviv Univ.
l. Sch., Israel). *Angiologica* 10(5-6):310-317,
73.

e angiographic features of leiomyomatous tumors
the small bowel are described in 3 cases (3 wo-
n, aged 34-66 yr). Selective celiac and superior-
senteric angiography disclose large, sometimes
ltiple, feeding arteries and draining veins.
ere are many irregular tumor vessels and dense
aining, venous pooling and early venous filling.
e margins are well circumscribed and correspond
the true size of the mass. The angiographic
fferential diagnosis between benign and malignant
iomyomatous tumors present considerable difficul-
es. The vascular pattern is similar. Demonstra-
on of more than one mass within the bowel wall
es not indicate malignancy, as multiple benign
sions may occur. If the lesion is larger than
cm in diameter, it is likely to be malignant.
wever, one of the 3 cases demonstrates that this
iterion is not absolute.

17 THE ANGIOGRAPHIC APPEARANCE OF GASTROIN-
TESTINAL CARCINOIDS. *(Ger.)* Vesin, S.;
nova, A. (Reg. Hosp., Prague-Bulovka, Czechoslo-
kia). *Fortschr. Geb. Roentgenstr. Nuklearmed.*
)(1):23-31, 1974.

66-yr-old man with a history of flush, diarrhea,
ight loss, and edema of the lower extremities pre-
nted with hepatomegaly, myogenic enlargement of
e heart, and arteriosclerosis. X-ray examination
the gastrointestinal tract showed a filling defect
cm in diameter at the ileocecal valve, circular
traction of the cecum, and displacement of the
omach and colon by the enlarged liver. Selective
giography of the superior mesenteric artery re-
aled a dilatation of the peripheral ileocecal
tery which opened into a network of tortuous arch-
ke or radiating arteries surrounding a highly
scularized structure measuring 4 x 6 cm. The con-
ast medium collected at the center of this struc-
re. An anomalous reaction occurred when 20 μg
repinephrine were injected intraarterially:
ood vessels constricted in the region of the tumor.
surgery a carcinoid was found which had infil-
ated the abdominal wall and metastasized into the
ver. A 51-yr-old woman who had received conser-
tive treatment for what appeared to be biliary disease was found to have many nodular hepatic metastases from a carcinoid at laparotomy. An attempt to locate the primary tumor by selective angiography of the superior mesenteric and celiac arteries was unsuccessful although the hepatic metastases were visible. At autopsy, performed 6 months later, 3 primary tumors measuring from 5.7 to 8 mm in diameter, were located in the intestinal submucosa 25-75 cm from the ileocecal valve. The presence of hepatic metastases was confirmed, and a few metastases were also detected in the mesenteric lymph nodes. Other findings included carcinoid fibrosis of the tricuspid and pulmonary valves of the heart, hypertrophic dilatation of the right side of the heart, and chronic peripheral venostasis. The failure to detect the primary tumors by angiography is attributed to their small size.

3618 NORMAL PYLORIC SPHINCTER COMPETENCE EVALUATION AS BASED ON 148 T-TUBE CHOLANGIOGRAMS. *(E.)* Feinberg. S. B.; Delaney, J. P. (Univ. Minnesota Hosps., Minneapolis). *Am. J. Gastroenterol.* 61(1):53-54, 1974.

The postoperative T-tube cholangiograms from 1964-1970 at the University of Minnesota Hospitals were reviewed. The cases included were free of gastric or duodenal pathology. In addition, those included had patent biliary trees, free spill into the duodenum as well as retrograde duodenal fill. The technique used is that of a gentle, slow hand injection of the water-soluble iodides in common use for i.v. pyelograms during those years. The injection is begun in the supine position with attention first directed to ampullary patency and free spill. Immediately thereafter, the patient is placed as steeply to the left, right, and anterolaterally as well as in the Trendelenburg position as might be needed to fill all primary radicals. The volume of contrast injected is limited to that required to fill the biliary tree and duodenum. All attempts are made to obviate ampullary spasm and pain. A total of 116 patients were studied who had a combined total of 148 postoperative cholangiograms. Of the 148, only 2 showed retrograde fill of the stomach. It is concluded that pyloric reflux is abnormal and not a physiologic variant.

3619 DETECTION OF CARCINOEMBRYONIC ANTIGEN IN FECES FOR THE DIAGNOSIS OF COLONIC RECTAL CANCERS. *(E.)* Hara, M.; Watanabe, S.; Kitagawa, M.; Yasutomi, M. (Osaka Univ. Hosp., Japan). *Am. J. Proctol.* 25(2):67-76, 1974.

Antisera for carcinoembryonic antigen were prepared by immunizing rabbits and guinea pigs with 0.6 M percholoric acid extracts from a colon adenocarcinoma and by absorbing each antiserum with normal colon homogenate, normal liver homogenate, perchloric acid extracts of normal spleen, and pooled human plasma. The rabbit and guinea pig antisera reacted not only with perchloric acid extracts of adenocarcinoma but also with extracts from normal as well as malignant feces. However, after absorption with fecal perchloric acid extracts, only guinea pig antiserum reacted with perchloric acid extracts from rectal and colonic carcinoma. Thus, it seems that tumor antigen preparation extracted from a colon adenocarcinoma contains cancer specific determinant and fecal determinant.

3620 ULTRAVIOLET ENDOSCOPY IN THE DIAGNOSIS OF UPPER GASTROINTESTINAL BLEEDING. *(E.)* Smith, B. H.; Berk, J. E. (Dept. Med., Univ. California, Irvine). *Am. J. Gastroenterol.* 60(6):549-556, 1973.

To establish the location of active gastrointestinal bleeding with greater certainty, fiberoptic esophagogastroduodenoscopy was employed using ultraviolet light and i.v. fluorescein. A total of 39 examinations was conducted on 35 patients. Each patient presented with acute upper gastrointestinal bleeding of unknown etiology and site when first seen. Of the 39 examinations, active bleeding manifested by clear visualization of blood emanating from a definitive lesion, or by a collection of fresh unclotted blood, was observed in 16 examinations by conventional endoscopy using white light. Ultraviolet endoscopy, by comparison, disclosed fluorescence indicative of free bleeding or oozing in 33 examinations. In 16 of the examinations, a single definitive lesion was detected on endoscopy; active bleeding was observed in 9 of these examinations by conventional endoscopy and in 13 by ultraviolet endoscopy. Multiple lesions were found in 22 of the examinations; free bleeding was detected in 7 of the latter by conventional endoscopy and in 19 by ultraviolet endoscopy. Ultraviolet endoscopy using i.v. fluorescein as a fluorescent marker provides diagnostic assistance in the problem of upper gastrointestinal bleeding by: 1) demonstration of active bleeding or continued oozing not obvious by conventional endoscopy using white light; 2) delineating the anatomical area of bleeding, if not the actual responsible lesion when these have not been clearly identified by ordinary examination; and 3) distinguishing which of several potential bleeding lesions is actively bleeding.

3621 STUDY OF THE ACCURACY OF HEPATIC SCINTIGRAPHY IN THE DIAGNOSIS OF METASTASES. *(Ger.)* Schwartz, K.-D.; Finck, W.; Fuchs, E.; Schülke, M. (Radiol. Clin., Univ. Rostock, Germany). *Z. Inn. Med.* 29(1):24-26, 1974.

GASTROINTESTINAL DISEASES

ESOPHAGUS

72 THE EFFECT OF DILUTE CORROSIVES ON THE ESOPHAGUS. *(E.)* Ashcraft, K. W.; Padula, T. (Univ. Texas Med. Branch, Galveston). *Pedia-ics* 53(2):226-232, 1974.

ie effect of dilute corrosive drain cleaners (less ian 10% concentration) on the esophagus was studied i thoracotomized mongrel cats. Sulfuric acid (9%), otassium hydroxide (8%), and sodium hydroxide (8.3%) il produced gross and microscopic evidence of severe image after 30-sec exposure. Sulfuric acid resulted i the most impressive gross injury. The burned muosa changed from pink to a white plaque-like discolortion along with wrinkling of the mucosa indicating nooth muscle spasm. Extensive coagulation was noted icroscopically. Potassium hydroxide produced marked ythematous injury with underlying muscle spasm. ie microscopic injury was complete liquefaction of ie mucosa with edema formation and mild inflammaion in the underlying muscularis mucosa and submucoil advential layers. Sodium hydroxide produced estruction of the superficial layer of squamous ucosa along with submucosal and transmural thrombois in blood vessels. The inflammatory response was ost marked with this product. It is suggested that resently allowable concentrations of these agents hould be banned. Clinical data on accidental injury n children indicate that child-proof packaging will ot afford much protection.

STOMACH

711 SIMIAN GASTROPATHY WITH SUBMUCOSAL GLANDS AND CYSTS: GASTRITIS GLANDULARIS OR CYSTI- PROFUNDA? *(E.)* Scotti, T. M. (Primate Pesticide ffects Lab., Research Triangle Park, N.C.). *Arch. thol.* 96(6):403-408, 1973.

unusual gastropathy with submucosal glands and sts, usually associated with mucus-secreting cell perplasia of the mucosa, was observed at autopsy 11 (52%) of 21 rhesus monkeys (*Macaca mulatta*), t in none of 9 squirrel monkeys (*Saimiri sciureus*). most instances, the gastric lesion occurred spon- neously, in contrast to similar lesions in monkeys the genus *Macaca* reported by other investigators, ich usually were attributed to known exposure to ritants. These lesions, characterized by promi- nt changes in the mucosa, including epithelial perplasia, and penetration of the mucosal epithe- ium into the submucosa, with formation of epithelial sts, were usually noted in animals exposed to poly- lorinated biphenyls (PCB) or triphenyls (PCT), iesel lubricating oil, and an intragastric parasitic ematode, *Nochtia nochti*. The amount and degree of nvasiveness of the submucosal epithelium were pro- ounced in 4 rhesus monkeys, moderate in 3, and slight 4. Of the 4 monkeys with pronounced submucosal in- olvement, 1 had received low-level doses of heptachlor .01 mg/kg p.o.) daily for 36 months and 1 had been ed high levels of PCB (500-2000 ppm/day) in the diet or 77 days prior to death. The 3rd monkey had received nly 1 p.o. dose of parathion (13 mg) 1 yr prior to death, hile the 4th monkey was without experimental exposure PBC or pesticides. No gastric lesions were found 2 rhesus monkeys that had low-level p.o. dose of DDT .5 mg/kg/day for 50 months) or parathion (0.3 g/kg/day for 52 months). No gastric disease of any ype was found in squirrel monkeys, including 3 given ow-level p.o. doses of pesticides (lindane, carbaryl, nd 2,4-D) and 1 fed high levels of PCB in the diet. hese lesions resemble observed gastropathy in man eported as diffuse heterotopic cystic malformation nd is analogous to colitis cystica profunda in man.

712 INDEPENDENT BEHAVIOUR OF BLOOD GROUP A- AND B-LIKE ACTIVITIES IN GASTRIC CARCINO- ATA OF BLOOD GROUP AB INDIVIDUALS. *(E.)* Denk, .; Tappeiner, G.; Holzner, J. H. (Sch. Med., niv. Vienna, Austria). *Nature* 248(5447):428- 30, 1974.

ive specimens of surgically removed gastric carcin- mata from patients with the blood group A_1B were tudied and independent behavior of the A and the B pecificity in 4 of them in certain areas of the malignant growth was observed. Histologically the tumors showed a variety of patterns from rather well-differentiated adenocarcinoma to anaplastic globocellular growth. Signet ring cells were present in 2 carcinomas. The normal superficial as well as the intestinal metaplastic mucosa were rich in both BG-A and BG-B in all of the 5 cases in a distribution typical for secretors. The endothelial cells of the blood vessels and the erythrocytes in the normal tissue as well as within the carcinoma were positive with respect to BG-A and BG-B in every case. No relationship between the presence of blood group substances and the histological degree of differentiation was observed in the cases and different distribution patterns of BG-A and -B activities were observed even in morphologically identical areas. Carcinoembryonic antigen was postulated to result from defective synthesis of blood group substances in gastrointestinal carcinomata due to genetic defects. α-N-acetyl-D-galactosaminyl transferase and α-D-galactosyl transferase, respectively, that attach the appropriate sugars in 1 → 3 linkage to the β-galactosyl unit in an H-active structure depend upon intact A and B genes, respectively. Since these transferases have identical acceptor substrate requirements the selective loss of either BG-A or BG-B is most likely to be due to deletion or repression of the corresponding gene in the ABO locus.

3713 EFFECT OF CARBENOXOLONE SODIUM ON ASPIRIN-INDUCED INJURY OF THE RAT GASTRIC MUCOSA. Yeomans, N. D.; St. John, D. J. B. (Alfred Hosp., Melbourne, Australia). *Am. J. Dig. Dis.* 19 (3):217-222, 1974.

Investigations were performed in male Sprague-Dawley rats to examine the effect of carbenoxolone sodium on aspirin-induced gastric mucosal injury. Mucosal damage was quantitated histologically in the body of the stomach (corpus) after a single dose of aspirin and after 2 weeks of daily aspirin. Over dosage ranges of 2-30 mg/kg/day of carbenoxolone and 10-120 mg/kg of aspirin, carbenoxolone treatment conferred no protection, despite evidence of a significant carbenoxolone effect on gastric mucus. This contrasts with the known protective action of carbenoxolone against injury by restraint stress and corticosteroids, and it is likely that these findings reflect such differences in pathogenesis.

3714 MANAGEMENT OF GASTRIC LYMPHOMAS. *(E.)* Connors, J.; Wise, L. (Washington Univ.

Sch. Med., St. Louis, Mo.). *Am. J. Surg.* 127(1): 102-108, 1974.

Between 1950 and 1970, 74 patients with primary gastric lymphoma were treated; these included 41 patients with lymphosarcoma, 29 with reticulum cell sarcoma, and 4 with Hodgkin's disease. The mean age was 61. The disease was more common in men; there were 28 women and 46 men. The 2 most common clinical features were pain and weight loss. The pain was often similar to that of peptic ulcer disease, localized to the epigastrium and relieved by ingestion of food and antacids. A gastric tumor was demonstrated in 49 patients, an ulcerating lesion in 8, and diffuse gastric involvement in 3. Of the 74 patients, 66 underwent exploration. Of the 66 patients who underwent exploration, in 38 the lesion was resected, but in 28 the lesion was unresectable. The rate of resectability in the patients who underwent operation was 57%; the total resectability rate for lymphosarcoma was 46%, for reticulum cell sarcoma 58%, and for Hodgkin's disease 50%. Twenty had perigastric nodal metastases and 18 did not. Patients with lymphosarcoma had a better prognosis than did those with reticulum cell sarcoma. In patients with resectable lesions the average tumor dose was 3,260 rads. Of the patients with gastrectomy and negative perigastric nodes, 5 received radiotherapy and 3 survived 5 years; 13 patients did not receive radiotherapy and 7 lived 5 years. Of the patients with gastrectomy and positive perigastric nodes, 6 received radiotherapy and 2 survived 5 years; 2 others are alive, however, at 33 and 48 months without evidence of residual disease. Fourteen patients with positive nodes did not receive radiotherapy and 3 survived 5 years. Twenty-eight patients had lesions that were considered unresectable. The average survival in this group was 10.9 months. Twenty-one of these patients received radiotherapy, with a mean tumor dose of 2,980 rads. The average survival in these patients was 13.3 months. Ten patients had extensive lesions requiring total gastrectomy. Four survived 5 years; 3 of these received from 2,500 to 3,500 rads postoperatively. A fifth patient is alive and well at 17 months. The operative mortality was 30% in this group. It is concluded that the diagnosis of primary gastric lymphoma should always be considered in the differential diagnosis of gastric lesions.

3715 URINARY PEPSINOGEN ZYMOGRAM IN GASTRECTOMIZED PATIENTS: WHAT IS THE SOURCE OF THESE PROTEASES?

(E.) Mangla, J. C.; Kim, Y. (Monroe Community Hosp., Rochester, N.Y.). *Am. J. Dig. Dis.* 19(3):211-215, 1974.

Urinary proteolytic activity and agar gel electrophoresis was done 3 months after complete gastrectomy in 7 patients, and the findings compared with those in 25 presumably normal subjects. It was found that 6 of the 7 gastrectomized patients showed proteolytic activity in the urine and that this enzymatic activity appears as 2 or 3 bands on agar gel electrophoresis. The origin of the urinary pepsinogens found in patients with complete gastrectomy, who are reputed not to have such activity, remains an enigma. The possible exaplanations are as follows: 1) Protease activity may originate from the duodenum, jejunum, esophagus, or seminal vesicles. 2) The pepsinogens may have arisen from ectopic gastric mucosa. 3) Liver, spleen, and many other tissues are supposed to produce cathepsin, but cathepsin is not excreted in the urine and was not seen in these cases. 4) Gastrectomy may not have been complete even though care was taken to select only those patients in which proximal and distal portions of excised stomach showed esophagus and duodenum, respectively. The presence of pepsinogen activity, however small, in gastrectomized patients as shown by this study would appear to be one reason why there is no correlation between peptic ulcer and uropepsin activity.

3716 IN VITRO DETERMINATION OF THE SENSITIVITY OF STOMACH CANCER TO 5-FLUOROURACIL.

(Rus. Savran, V. R. (L'vov Med. Inst., USSR). *Vrach. Delo* (1):80-82, 1974.

In vitro tests for sensitivity to 5-fluorouracil were performed on tumors removed from 105 patients (64 men and 41 women) with stomach cancer. After removin fat, connective tissue, and necrotic areas, tissue was incubated in tubes containing Ringer-Locke's solution (controls) or 5-fluorouracil (2.5 and 5 mg/ml) at 37 C for 24 hr. Then 3 ml of an indicator solution was added to detect dehydrogenase activity. This solution contained 1% agar in 1/15 M pH 7.2 phosphate buffer, 0.4% glucose, and methylene blue (1:30,000). Tubes were incubated at 37 C until the solution became colorless. Of 105 tumors, 38 showed *in vitro* sensitivity to 5-fluorouracil. The most sensitive tumors were those located in the antrum (20 of 52 or 38.5%) and the corpus (3 of 10); only 1 of 5 tumors in the cardia was sensitive to 5-fluorouracil. No difference was found between the sensitivity of exophytic tumors (15 of 37 or 40.5%) and infiltrating tumors (20 of 54 or 37%); only 3 of 14 (21.4%) ulcerated tumors were sensitive. Adenocarcinomas were sensitive in 28 of 75 cases (37.3%) and scirrhous carcinomas in 5 of 14 cases (35.7%). All 7 colloid carcinomas were resistant to 5-fluorouracil. Since most patients were treated surgically, it was possible to compare the results of the *in vitro* test with the results of chemotherapy in only 26 patients. Administration of 5-fluorouracil (15 mg/kg i.v. every 48 hr) had no effect on 18 tumors which were resistant to this agent in the *in vitro* test. Tumor regression occurred in 4 of the 8 remaining patients, while no response was obtained in the other 4 patients.

STOMACH

Peptic Ulcers

3749 DUODENAL ULCER IN THE RAT. *(E.)* Kowalewski, K. (Surg.-Med. Res. Inst., Univ. Alberta, Edmonton, Canada). *Lab. Anim. Sci.* 24(1): 39-42, 1974.

Male adult rats with permanent gastric cannulas were infused i.v. for 24 hours with pentagastrin and the cholinergic drug bethanechol chloride, administered separately or combined. In the first series of rats, gastric cannulas were opened and 24 hour secretions were collected during stimulation. In the second series of rats, similarly treated, the gastric cannulas were closed and the juice permitted to flow over the duodenal mucosa. In the third series, rats were infused intragastrically with exogenous gastric juice from a juice pool obtained from rats treated for 24 hours with pentagastrin and the cholinergic drug bethanechol chloride. Duodenal ulcers occurred only in the series of animals with gastric cannulas closed and in rats infused intragastrically with exogenous hydrogen ion-rich juice. It appears that the rat can develop duodenal ulcer if there is sustained exposure of the duodenal mucosa to hyperacidic, voluminous gastric secretion.

3750 BACK DIFFUSION OF HYDROGEN IONS ACROSS GASTRIC MUCOSA OF PATIENTS WITH GASTRIC ULCER AND RHEUMATOID ARTHRITIS. *(E.)* Ivey, K. J.; Clifton, J. A. (Roy. Prince Alfred Hosp., Sydney, Australia). *Br. Med. J.* 1(5896):16-19, 1974.

Ionic permeability of the gastric mucosa was measured in 6 patients with an acute exacerbation of severe generalized rheumatoid arthritis receiving either aspirin and prednisone or aspirin and indomethacin as therapy. The results were compared with those in 4 patients with benign gastric ulcer and 9 normal subjects. Compared with controls, H^+ concentration was decreased and Na^+ concentration increased while corrected H^+ flux out of the lumen and Na^+ flux into the lumen were significantly increased in the patient groups, indicating increased mucosal permeability. Abnormality of the gastric mucosal barrier persisted in 2 patients despite healing of their ulcers. Mucosal permeability of patients with rheumatoid arthritis and gastric ulcer did not differ significantly from one another. One rheumatoid patient with a gastric ulcer showed no difference in mucosal permeability to that of the other rheumatoid patients.

e studies suggest that increased H^+ ion loss
ributes to the apparent hyposecretion of acid
atients with gastric ulcer; persistence of an
rmal gastric mucosal barrier to H^+ ions may ex-
n the high recurrence rate of gastric ulcers;
an abnormal gastric mucosal barrier may be a
ursor to gastric ulceration in rheumatoid arthri-

ANASTOMOTIC ULCERATION.

(E.) Cleator,
I. G. M.; Holubitsky, I. B.; Harrison, R.
Dept. Surg., Univ. British Columbia, Vancouver,
da). *Ann. Surg.* 179(3):339-351, 1974.

e were 331 patients who were treated for 390
odes of anastomotic ulceration at 2 Vancouver
itals. These patients were followed and
ing treatments for their anastomotic ulceration
evaluated in terms of mortality and recur-
e rate. The overall death rate from ulcer or
treatment was 6% of the 331 patients, and 15% had
rther ulcer recurrence after surgical treatment.
he group treated surgically for a second ulcer,
developed a third ulcer. One patient developed
th and fifth anastomotic ulcers. Barium meal
effective in diagnosing 51% of the 321 anastomot-
lcers in which this examination was carried out.
acid output studies were most useful in the post-
rectomy with or without vagotomy groups: a
l of over 12 mEq. was diagnostic of hypersecretion
was present in 40% of the patients with anastom-
ulcers. Gastroscopy gave a positive result in
33% of the 72 instances in which it was employed;
was in the prefiber-optic era. Of the patients
anastomotic ulcer, 74% had prandial pain and 56%
l or more episodes of hemorrhage. Perforation of
nastomotic ulcer was present in 5% of the patients,
ructive symptoms in 9%, and gastro-jejunocolic
ulae in 2%. There were no patients with secreting
rs of the pancreas or parathyroid. Of 140 Bill-
II anastomotic ulcers, 6% had retained antrum in
duodenal stump. After comparison of the mortality
recurrence rate of the various treatment options
lable in this and other studies, it is concluded
vagotomy is the treatment of choice for post-
rectomy anastomotic ulcer, for postvagotomy and
nage anastomotic ulcer and for postgastrectomy
vagotomy anastomotic ulcer. It is also
luded that partial gastrectomy alone is
treatment of choice for postgastroenterostomy
tomotic ulcer.

SALIVARY SECRETION IN SUBJECTS WITH DUODENAL ULCER.

(E.) Andre, C.; Descos, F.;
e, F.; Lambert, R. (Edouard Herriot Hosp., Lyon,
ce). *Digestion* 9(6):525-531, 1973.

thy subjects and patients suffering from an evolu-
duodenal ulcer were compared with respect to
uts of organic and inorganic components of saliva.
r stimulation of the salivary and pharyngeal se-
ion by a collection tube that was positioned in
stomach, the volume of saliva and the hexosamines,
ic acid, sulfate, total proteins, potassium and
free calcium outputs were lower in duodenal ulcer patients than in controls. The differences were not observed when the salivary secretion was collected in patients chewing Parafilm, when pharyngeal secretion was not stimulated by the collection tube in the stomach.

3753 GASTRIC ACIDITY UROPEPSIN AND URINARY 17-KETOSTEROIDS IN BURNS.

(E.) Mathur, P. N.; Singh, P. P.; Rathore, A. S.; Shastri, K. D. (R.N.T. Med. Coll., Udiapur, India). *Indian J. Med. Res.* 61(11):1618-1624, 1973.

Gastric secretions, acidity, uropepsin, and urinary 17-ketosteroids were measured in 35 burn patients on postburn days 3, 10, and 17. All were elevated on the third postburn day. The elevations were greatest in the group with more than 30% burn injury who died after day 17 due to massive exanguinating gastrointestinal hemorrhage. They decreased progressively in patients with less than 30% burn injury, returning to almost normal by postburn day 17. In other patients, they were maximum on the 10th day and decreased on the 17th day regardless of the clinical condition, thus suggesting adrenal insufficiency. It appeared that hyperactivity of the adrenal cortex in burn stress induced hyperacidity, and it was concluded that corticosteroid therapy in small doses would be beneficial in acute burns.

3754 IMMUNOLOGICAL REACTIONS IN PEPTIC ULCER.

(Rus.) Kalenskii, V. Kh. (Khar'kov Med. Inst., USSR). *Vrach. Delo* (2):77-80, 1974.

Autoimmunity was studied in 120 patients (88 men and 32 women, aged 18-60 yr) with peptic ulcers. These consisted of 110 patients with duodenal ulcers and 10 with stomach ulcers. Ouanier's reaction, a measure of autoimmunity of the immediate type, demonstrated that 99 of the 115 patients tested (86.1%) had circulating antiorgan antibodies. Using gastric and duodenal tissues from these patients as antigen, the *in vitro* lymphocyte transformation test, a measure of autoimmunity of the delayed type, was positive in 107 of 120 cases (89.2%). The extent of transformation differed: it was greatest in patients with long histories of ulcers and in those with evidence of scar formation. An inverse relation was found between the results from Ouanier's reaction and those of the lymphocyte transformation test. In most cases the level of humoral autoantibodies was highest in those with less pronounced cellular autoimmunity. When an increase occurred in the level of circulating autoantibodies during therapy, symptoms disappeared rapidly, while symptoms persisted if cellular autoimmunity remained the same or increased. These findings suggest that circulating autoantibodies might be responsible for manifestations of peptic ulcer, but that at a certain stage they assume a protective role by suppressing cellular autoimmunity.

3755 A PROSPECTIVE STUDY OF STRESS ULCERATION IN VIETNAM. *(E.)* Bowen, J. C.; Fleming, W. H. (Walter Reed Army Inst. Res., Washington, D. C.). *South. Med. J.* 67(2):156-160, 1974.

In an attempt to elucidate the pathogenesis of stress ulceration, a prospective study was undertaken among combat casualties in Vietnam. Of 2720 patients undergoing operations, 37 (14%) meeting the following criteria were selected: 1) severe injury, 2) no gastric or duodenal injury, 3) expected to remain at an evacuation hospital for at least 5 days, and 4) added to study if systemic sepsis developed at the hospital. Of the patients studied, 19 bled from the stress ulcer, 9 required transfusion, 4 required gastric resection, 2 rebled postoperatively, and 7 died. Four of these deaths were related to stress ulcers. Gastroscopic findings in 15 high-risk patients indicated multiple superficial erosions in 11, craters in 9, and no ulcers in 4. Twenty eight different substances considered as possible mediators of stress ulcer were measured in the blood, urine, or gastric juice, but none showed any significant, or even suggestive, correlations with the presence or absence of either bleeding or endoscopically demonstrated ulcerations. A significant difference was demonstrated between the levels of serum gastrin with and without central nervous system injury, but no correlation was found between stress ulceration and either gastrin or central nervous system injury. The failure in this study to identify specific etiologic factors which correlate with the appearance of upper gastrointestinal bleeding supports the observation that many of the patients had evidence of stress ulceration gastroscopically, even though they did not have gross hemorrhage. This suggests that local rather than systemic factors may play a large role in determining the degree of ulceration and hemorrhage. It seemed likely that acid in the lumen of the stomach under conditions of stress probably potentiates the injury to the gastric mucosa.

SMALL INTESTINE

3803 TUBERCULOUS ENTERITIS. A REPORT OF THREE PATIENTS. *(E.)* Moss, J. D.; Knauer, C. M. (Santa Clara Valley Med. Ctr., San Jose, Calif.). *Gastroenterology* 65(6):959-966, 1973.

Case reports are presented for 3 patients with tuberculous enteritis; 2 developed the rare complication of free intestinal perforation. All 3 patients, aged 6, 29, and 35 yr, had recently emigrated from Mexico and had active pulmonary tuberculosis with radiological evidence of intestinal involvement. Symptoms which occurred in these patients included weight loss, anorexia, abdominal distention, fever, and iron-deficiency anemia. In one patient the diagnosis was established on the basis of caseating granulomas with acid-fast bacilli found in the mucosa, submucosa, muscularis, and serosa of the small intestine. Surgical specimens were not available for the other 2 patients, but one of them had radiological evidence of miliary pulmonary tuberculosis, noncaseating granulomas in a liver biopsy, acid-fast bacilli in both stool and gastric washings, and a good response to antituberculous therapy. The remaining patient had radiological evidence of tuberculosis and developed increasing abdominal symptoms after a pulmonary cavity developed. This patient had been treated for rheumatoid arthritis for 3 yr with adrena corticosteroids and salicylates before developing symptoms of tuberculosis. She developed resistance to isoniazid, streptomycin, and p-aminosalicylic acid and had to be treated with ethionamide and ethambutal Latex fixation and lupus erythematosus tests were pos

. The youngest patient had several episodes of small
l obstruction with abdominal distention and, on
occasion, peritoneal free air which cleared on
ervative management. The oldest patient developed
toms of a perforated viscus and, at laparotomy,
generalized peritonitis with 3 small bowel per-
ations and a serosa studded with tubercles.
orations were closed surgically, but the patient
a very stormy postoperative course which required
re surgical procedures. Complications consisted
variety of systemic bacterial and fungal infec-
s. Tuberculous enteritis should be considered in all
ents with abdominal masses that present clinically
ographically, particularly in the presence of pul-
ry disease.

INTESTINAL BYPASS IN MORBID OBESITY. *(E.)*

Corso, P. J.; Joseph, W. L. (George Wash-
on Univ. Med. Ctr., Washington, D.C.). *Surg.*
col. Obstet. 138(1):1-5, 1974.

4 massively obese patients (289-485 pounds) an
stinal bypass procedure induced weight loss
ly with a lack of significant metabolic abnor-
ties. Criteria for selection of candidates for
noileal bypass were 2 to 3 times ideal weight
a period of at least 3 yr; failure of dietary
mens or exercise programs; absence of any correc-
e endocrinopathy; absence of other diseases or
rmalities which might increase the operative risk
ypass; patient understanding and cooperation; and
ence of certain complications or diseases com-
y associated with obesity which might be allevi-
by a significant reduction in weight. All
ents underwent operation through a long abdominal
ine incision. The bypass procedure consisted
n end-to-end anastomosis of the proximal part
he jejunum to the distal part of the ileum.
distal end of the bypassed jejunoileum was drained
nastomosis to the sigmoid colon. The proximal
ion of the bypassed jejunum was used to close
mesenteric defect posterior to the jejunoileo-
y. This technique prevented not only internal
iation of the bypassed intestine but also pos-
e intussusception postoperatively. There have
no operative deaths, and all the patients were
lable for follow-up studies. Problems with
d healing occurred in 1/3 of the patients. Di-
ea was a regular problem in the immediate post-
ative period. A low-fat diet, restriction of
ds with meals, and the occasional use of small
nts of paregoric or diphenoxylate hydrochloride
lted in adequate control. The majority of pa-
ts averaged a 20-25 pound decrease in weight
r the operation and the catabolic state induced
he immediate postoperative period. The greatest
ction in weight occurred during the 1st yr (79-
pounds). This loss of weight occurred without
ges in dietary habits since all the patients
continued to consume the same large quantities
ood they did prior to the bypass operation.
e who were hypertensive preoperatively still re-
e antihypertensive medications, but to a lesser
ee. Jejunoileal bypass reduced carbohydrate
rption. In 5 of 7 patients with a preoperative
etic glucose tolerance curve, there was a flat-
ng of the curve into the normal range. Malabsorption of fat was apparent from the large increase in fecal fat. There was also a fall in serum triglycerides and cholesterol levels. Serum magnesium, calcium, and potassium levels remained stable. The serum carotene level remained consistently low (30-40 mg%). It is concluded that with the technique described, a satisfactory rate of loss of weight can be obtained with minimal side effects and no mortality.

3805 GLUCAGON, GASTRIN, AND CARCINOID TUMORS OF THE DUODENUM, PANCREAS, AND STOMACH: POLYPEPTIDE "APUDOMAS" OF THE FOREGUT. *(E.)*

Friesen, S. R.; Hermreck, A. S.; Mantz, F. A., Jr. (Univ. Kansas Med. Ctr., Kansas City). *Am. J. Surg.* 127(1): 90-101, 1974.

The clinical and investigative findings in 11 selected patients are presented which illustrate various degrees of functional activity of polypeptide-secreting amine precursor uptake and decarboxylation cell endocrinopathies of the foregut. Six patients with carcinoid tumors presented with as many different clinical pictures, including the Zollinger-Ellison syndrome, hyperparathyroidism, the carcinoid syndrome, the familial multiple endocrine adenomatosis syndrome, Cushing's syndrome, and hyperglucagonism with diabetes. Four patients with diabetes and nonbeta islet cell carcinoma are presented in whom presumptive and assay evidence implicates glucagon activity of the tumors. Two patients with amine precursor uptake and decarboxylation cell abnormalities (one with diarrheogenic islet cells hyperplasia and one with duodenal paraganglioma) and in whom no known polypeptides have been identified are also presented. The embryologic, cytochemical, and functional capabilities of the neuroendocrine cells of the foregut are interrelated, and when these cells are hyperplastic or neoplastic, they may produce unusual clinical pictures which are more easily diagnosed by bioassay and immunochemical than by histologic methods.

3806 INTESTINAL LYMPHOMA WITH UNUSUAL SEQUENCE OF SERUM IgA CHANGES. *(E.)*

Shaklai, M.; Mintz, U.; Pinkhas, J.; Pick, A.; Ben-Bassat, M.; DeVries, A. (Tel-Aviv Univ. Med. Sch., Israel). *Am. J. Dig. Dis.* 19(3):279-286, 1974.

A 32-yr-old woman with Mediterranean lymphoma presented in the course of her fatal disease an unusual sequence of quantitative serum IgA changes but at no time free alpha chains. The patient was further remarkable in that she developed a cervical lymphadenopathy of Hodgkin's disease type, which was reversed by chemotherapy without cure of the intestinal lymphoma. During the 3 yr of observation, the patient had marked hypoproteinemia and hypoalbuminemia. Noteworthy is the sequence of the changes in the serum IgA from a marked elevation early in the illness, through an undetectable level, to a reappearing marked increase. Serum IgG remained normal throughout the course of the disease; the serum IgM was low throughout. Jejunal biopsy revealed a massive cellular infiltrate in the intestinal mucosa, consisting of 2 types of cells: monomorphous lymphocytic cells revealing a small nucleolus and a fine chromatin pattern, and a small number of plasma cells. The histological diagnosis was malignant lymphoma, lymphocytic type. Histological sections taken from the small bowel revealed a diffuse heavy cellular infiltration of the intestinal mucosa along its entire length, with a slight local invasion of the muscularis mucosa. Marked villus atrophy and loss of glandular elements of the intestinal mucosa were noted. The Hodgkin's type cervical lymphadenopathy that developed in the course of the disease is considered to have represented an additional malignant clone appearing consequent to immunological deficiency.

3807 HEPATIC EFFECTS OF JEJUNOILEAL BYPASS FOR MORBID OBESITY. *(E.)* Brown, R. G.; O'Leary, J. P.; Woodward, E. R. (Univ. Florida Coll. Med., Gainesville). *Am. J. Surg.* 127(1):53-58, 1974.

Experience with 37 intestinal bypass operations in 36 patients is reported. Documented severe liver failure occurred in 6 patients with 1 death. The failure is manifested by the onset of anorexia, nausea, crampy abdominal pain, and vomiting. The earliest detectable functional abnormality appears to be a decrease in uptake of technetium sulfa colloid by the liver. BSP retention is followed by hypoalbuminemia and hypokalemia. Elevation of the SGOT, SGPT, and alkaline phosphatase levels may occur at this time. Fluid retention with weight gain, peripheral edema, and ascites is rapidly followed by hyperbilirubinemia of the conjugated type. Lesser degrees of abnormal liver function were discovered in 8 other patients. Halothane anesthesia, hepatitis-associated antigen, alcoholism, and diabetes do not appear to be factors.

3808 AORTOENTERIC AND PARAPROSTHETIC-ENTERIC FISTULAS: PROBLEMS OF DIAGNOSIS AND MANAGEMENT. *(E.)* Elliott, Jr., J. P.; Smith, R. F.; Szilagyi, D. E. (Henry Ford Hosp., Detroit, Mich.). *Arch. Surg.* 108(4):479-490, 1974.

The clinical characteristics, surgical treatment, and therapeutic results were surveyed in 11 cases of aortoenteric and 8 cases of paraprosthetic-enteric fistulas observed in 2085 abdominal aortic reconstructive operations. The clinical manifestations of these lesions were exsanguinating hemorrhage or medically uncontrollable retroperitoneal sepsis. The diagnosis of aortoenteric or paraprosthetic-enteric fistulization must be assumed in every case of abdominal aortic reconstruction with late hemorrhagic or septic complications. The indicated treatment is early and aggressive surgical intervention supported with appropriate antibiotic medication. Some operative technical details appear useful in reducing the probability of occurrence of these complications. In the case of dense adherence between the duodenum and the aneurysmal sac, the freeing of the duodenum must be omitted and a part of the aneurysmal sac left on the duodenal wall. To avoid erosion of the duodenal wall, live, well-vascularized tissue should be interposed between the duodenum and the graft.

3809 LIVER BIOPSY FINDINGS IN SEVENTY-SEVEN CONSECUTIVE PATIENTS UNDERGOING JEJUNOILEA BYPASS FOR MORBID OBESITY. *(E.)* Buchwald, H.; Lober, P. H.; Varco, R. L. (Univ. Minnesota Med. Sch., Minneapolis). *Am. J. Surg.* 127(1):48-52, 1974.

Liver biopsies were performed on 11 male and 66 female morbidly obese patients to clarify the status of hepatic morphology existent at the time of jejunoileal bypass. All results of preoperative liver function tests were within normal limits. Twenty-eight of the patients (36%) had a normal liver morphology; 24 had less than 25% fatty infiltration; 9 had 25 to 50% fatty infiltration; 16 had greater than 50% fatty infiltration; and no patient exhibite fibrosis. None of the 11 males had normal liver architecture. Fatty infiltration was represented by intracellular hepatocyte vacuolization. No significant disturbances in hepatic architecture were observed in these biopsy sections. There appears to be a definite positive correlation of the degree of fatty liver infiltration with the percentage of overweight. The more obese the patient, the more likely the demonstration of fatty changes in the liver, and the average percentage of fat present in the liver rises as a function of the increase in excess weight.

3810 MAGNESIUM METABOLISM IN MAN WITH SPECIAL REFERENCE TO JEJUNOILEAL BYPASS FOR OBESIT *(E.)* Swenson, Jr., S. A.; Lewis, J. W.; Sebby, K. R. (Univ. Nebraska Coll. Med., Omaha). *Am. J. Surg.* 127(3):250-255, 1974.

The current knowledge of metabolic pathways of magnesium are discussed and cases are presented in which the altered metabolism of magnesium is of clinical importance. An adult maintains a body content of approximately 20-30 g of magnesium. The most well-known action of magnesium is its effect on the neuromuscular junction. Magnesium repletion leads to a decrease in neuronal excitability; depletion leads to an increase in excitability. Magnesium serves as an activator for many enzyme systems of intracellular metabolism. Most important among these enzymes are those that hydrolyze and transfer phosphate groups, including the enzymes concerned with reactions involving adenosine triphosphate. Magnesium is essential in the synthesis of protein, being necessary for DNA, RNA, and ribosomal function. Absorption begins within 1 hr of ingestion and continu at as steady rate for 2-6 hr with little absorption taking place after 12 hr. The kidney is the principal organ in the homeostasis of the magnesium ion. In severe renal disease there is a decrease in the amount of magnesium ion filtered by the kidney. Magnesium seems to be controlled by a variety of hormones in the body. Parathormone increases the serum level of magnesium. Thyrocalcitonin lowers the serum level of magnesium and decreases the urinary excretion of magnesium. Hyperaldosteronism has been associated with hypomagnesemia. Hypomagnesemia has been found in some patients with hyperthyroidism. The diagnosis of magnesium deficiency is usually made after either a chronic, inadequate, or excessive loss of magnesium. The clinical manifestations of hypomagnesemia are neuromuscular irri-

ility and central nervous system hyperirritability.
:al aberrations are also prominent. Hypertension
developed in some patients who were previously
otensive. Other changes include personality
nges, muscle weakness, vertigo, and tetany. Con-
ions that lead to magnesium depletion include:
trointestinal malfunction, diuretic therapy,
longed use of i.v. fluids without magnesium sup-
mentation, severe infections, and chronic alco-
ism. Therapy for hypomagnesemia is indicated
there are clinical symptoms and depressed
m or tissue levels. Hypermagnesemia usually re-
ts from increased intake with poor renal function
from treatment of toxemia of pregnancy. The symp-
s of hypermagnesemia are usually lethargy, uncon-
ousness, hypotension, and hyperreflexia. Five
e reports are presented of patients with magnesium
letion. Hypomagnesemia in these cases was of
rogenic origin, as all had undergone small bowel
ass for obesity.

ROTATIONAL ABNORMALITIES OF THE GUT: RE-
EMPHASIS OF A NEGLECTED FACET, ISOLATED
MPLETE ROTATION OF THE DUODENUM. *(E.)* Firor, H.
Harris, V. J. (Cook County Hosp., Chicago, Ill.).
J. Roentgenol. Radium Ther. Nucl. Med. 120(2):
-321, 1974.

omplete rotation of the duodenum with normal ro-
ion of the colon is a significant facet of the
rotation syndrome. Lack of fixation of the right
on may accompany this abnormality. When this is
sent, midgut volvulus may occur; this is uncommon.
s abnormality presents with vomiting as the prin-
al symptom. The onset may be in infancy or as
e as adult life. Upper gastrointestinal contrast
dy is the only examination required to make this
gnosis. Treatment consists of mobilization of
colon into the nonrotated position, lysis of the
denum, and ruling out an intrinsic duodenal ob-
uction.

2 MALIGNANT CARCINOID TUMOUR WITH GANGRENE
OF THE SMALL INTESTINE. *(E.)* Murray-Lyon,
M.; Rake, M. O.; Marshall, A. K.; Williams, R.
ng's Coll. Hosp., London, England). *Br. Med. J.*
395):770-771, 1973.

e histories are presented of 4 patients with a
ignant carcinoid tumor of the small bowel (3 had
carcinoid syndrome) who developed gangrene of
small intestine. Three of the patients had ex-
s 5-hydroxyindole secretion. The development of
grene of the small intestine may be difficult to
ognize and distinguish from the other causes of
ominal pain associated with carcinoid tumors, but
prolonged and constant quality of the pain may
of diagnostic help. Although all 4 of the patients
d, recognition of this complication should lead to
lier laparotomy with the chance of resecting the
ected segment of bowel. A prominent feature in
cases was a proliferation of elastic tissue in
adventitia and intima of the mesenteric vessel,
the vessel lumens were not much narrowed, and
s alone does not seem sufficient to account for
development of gangrene. In 2 of the cases, thrombosis of mesenteric vessels had probably also occurred and this, together with restriction of mesenteric flow due to pressure by tumor tissue and the striking fibrous reaction in the root of the mesentery, is likely to be more important. The pathogenesis of the characteristic fibrous reaction is unknown.

3813 INTESTINAL INJURIES INCIDENTAL TO IRRADIATION OF CARCINOMA OF THE CERVIX OF THE UTERUS. *(E.)* Schmitz, R. L.; Chao, J. H.; Bartolome, Jr., J. S. (Mercy Hosp. Med. Ctr., Chicago, Ill.). *Surg. Gynecol. Obstet.* 138(1):29-32, 1974.

Most irradiation injuries to the intestinal tract are incidental to therapy given for carcinoma in the cervix uteri or endometrium. While temporary nausea, vomiting, cramping, and diarrhea are common, significant injury occurs in less than 5% of the cases. If the exposure is in small dosages at long intervals in a total amount less than 4000 r, the effects are not severe. However, if the exposure is in larger dosages at shorter intervals, in a total amount exceeding 4500 r, the effects are proportionately more severe. When the dosage is heavy enough in a localized area, necrosis of the intestine may occur with hemorrhage, sloughing or perforation. After the acute reaction to such heavy dosages subsides, an endarteritis develops, followed or accompanied by atrophy and cicatrization. Thirty-seven patients with irradiation injuries were treated. The clinical symptoms were those of colitis. The injury occurred in the ileum 14 times, in the sigmoid 3 times, and in the rectum 20 times. In 29 patients, the primary disease was in the cervix uteri and in 8 patients, in the endometrium. The types of injury include enterocolitis, local ulceration, rectovaginal fistula, atrophy, and neoplasia. A wide range of methods of treatment is necessary in treating patients with these injuries. In some instances, vigorous conservative management is sufficient to heal rectal ulcers. This includes transfusions, bland diet, opiates, corticosteroids, stool softeners, and warm oil enemas. In other instances, temporary diversionary colostomy will be necessary for 6 to 12 months to permit healing. Diversionary operations included temporary loop colostomy, end-on sigmoid colostomy, or internal ileotransverse colostomy. Most operations were resective in nature and had the advantage of removing the diseased tissue for microscopic analysis. There were 2 hospital deaths in the series.

3814 URINARY TRACT STONE AFTER SMALL BOWEL BYPASS FOR MORBID OBESITY. *(E.)* O'Leary, J. P.; Thomas, Jr., W. C.; Woodward, E. R. (Univ. Florida Coll. Med., Gainesville). *Am. J. Surg.* 127(2):142-147, 1974.

The incidence, type of urinary tract stone, and the pathophysiologic aspects of its production were studied in 31 morbidly obese persons who had undergone small bowel bypass. Nine patients had end-to-end jejunoileal shunts and 22 had end-to-side jejunoileal shunts. In 7 of the 31 patients (3 males and 4 females), urinary tract stones developed.

Four of these patients had symptoms of calculi, but in 3 patients the stones were detected on routine roentgenography. One patient had had a stone previously, but the composition of the stone had changed from magnesium-ammonium-phosphate to calcium oxalate after bypass. Another patient had had a stable, small, radiopaque stone for 13 yr and it had enlarged since the operation. Six patients were fed a constant 1700 kcal diet for 1 to 6 weeks. All patients demonstrated marked hyperoxaluria on the first 24 hr collection of urine. Two patients with renal calculi were treated with taurine (2.0 g 4 times daily) and 2 were treated with cholestyramine (4.0 g 3 times daily) for at least 4 days. These patients had no change in urinary excretion of oxalate. All patients had marked steatorrhea. Efforts to reduce additional formation of stones in those patients with bypass and with calculi have been limited to correction of the acidosis, reduction of the caloric intake, and avoidance of excessive amounts of those liquids containing large amounts of soluble oxalate such as tea and fruit juices.

3815 LEIOMYOMAS OF THE SMALL INTESTINE. *(Fr.)*

Mabille, J. P.; Cortet, P.; Gaudet, M.; Seigneuric, C.; Gambert, B. (Univ. Hosp. Ctr., Dijon, France). *Ann. Radiol. (Paris)* 16(11/12): 773-779, 1973.

A 59-yr-old woman had 4 episodes of melena over a 1-yr period and symptoms suggestive of König's syndrome. Although no abnormalities were found in intestinal transit, superior mesenteric arteriography revealed the presence of a well vascularized benign tumor on the outside of the small intestine. At surgery an exoluminal tumor was found in the mesentery about 60 cm from the ileocecal valve. It was an intestinal leiomyoma with no evidence of malignancy. A 44-yr-old woman with an 8-yr history of melena, hypochromic anemia, and symptoms suggestive of König's syndrome had a tumor the size of a grapefruit in the left hypochondrium. A barium swallow showed that this tumor was located in the jejunum. At surgery the tumor was found in the duodenojejunal angle. It compressed the first loop of the small intestine in the front and adhered to the transverse mesocolon, peritoneum, and lower pole of the left kidney in back. No peritoneal or hepatic metastases were detected. Although clinical and radiological findings suggested that the tumor was a lymphoreticulosarcoma, histological examination revealed that it was a leiomyoma which had undergone edematous, necrotic, and hemorrhagic changes.

3816 JEJUNOILEAL BYPASS FOR MASSIVE OBESITY: RESULTS AND COMPLICATIONS IN FIFTY-TWO PATIENTS. *(E.)*

Fikri, E.; Cassella, R. R. (Western Pennsylvania Hosp., Pittsburgh). *Ann. Surg.* 179(4): 460-464, 1974.

Between 1967 and 1972, 52 patients (47 females and 5 males with an average age of 30 yr) underwent jejunoileal bypass for morbid obesity in one hospital. The majority of the patients were 140-240 pounds above the ideal weight. The average duration of hospitalization was 14 days. The average loss in preoperative body weight was 39% after jejunoileal bypass. The body weight stabilized after 18-30 months postsurgery, and three patients gained 15-30 pounds 1-3 years after their weight had stabilize Operative complications included major and minor wound infections, atelectasis, pneumonia, pulmonary embolism, pancreatitis, high output enterocutaneous fistural, and, in one case, death. Delayed complications after jejunoileal bypass included incisional hernias, hepatocellular insufficiency, fatty metamorphosis of the liver, diarrhea, intussusception, dilatation of the colon, electrolyte imbalance, and recurrent urinary tract calculi. Two patients died of cardiac arrest and liver failure. Twenty patient had hypertension before bypass; after bypass, 11 became normotensive and 8 showed improvement. Five patients were preoperatively diabetic; after bypass, 2 no longer required medication and the dose of insulin was reduced in the other 3. Forty-five patien had hypercholesterolemia prior to bypass; after surgery the serum cholesterol levels dropped to a range of 90-150 mg%. The majority of patients were please with the results and enjoyed improved psychological, social, and economic adjustment.

3817 INTESTINAL OBSTRUCTION IN THE NEONATE DUE TO VITELLINE DUCT CYSTS. *(E.)*

Grosfeld, J. L.; Franken, E. A. (Indiana Univ. Sch. Med., Indianapolis). *Surg. Gynecol. Obstet.* 138(4):527-532, 1974.

An incomplete form of intestinal obstruction was observed in 3 neonates. In all 3, the abdominal mass was caused by vitelline duct cysts which were characterized by the delayed onset of abdominal distention, bilious vomiting, and the presence of a palpable abdominal mass. The mass was located in the midportion or right side of the abdomen. Roentgenograms of the abdomen demonstrated a cystic mass with either an air-fluid level or a soap-bubble appearance and evidence of partial obstruction of the small intestine in each instance. Lateral roentgenographic views of the abdomen confirmed the relation of the vitelline cyst to the umbilicus. Barium enema studies demonstrated a normal caliber colon and indicated that the mass was not of colonic origin. Surgical treatment varied in each instance, depending on conditions present at the time of operation. In the first patient, simple V-shaped resection of the base of the cyst from the normal ileum and transverse ileoplasty were required. In the second patient, extensive intestinal resection, temporary enterostomy formation, and end-to-end anastomosis were required to reestablish intestinal continuity. In the last patient, the base of the cyst was quite large, requiring intestinal resection along with the cyst and a primary end-to-end ileal anastomosis. In each patient, operative therapy provided satisfactory results. Diagnosis of communicating vitelline duct cyst should be suspected in infants if the characteristic clinical and roentgenographic patterns are observed.

3818 NEW PARAMETERS OF VIABILITY IN ISCHEMIC BOWEL DISEASE. *(E.)*

Katz, S.; Wahab, A.; Murray, W.; Williams, L. F. (Boston Univ. Med. Ctr., Mass.). *Am. J. Surg.* 127(2):136-141, 1974.

values of electromyography, pH determination, and
azolium analysis of the mucosa were assessed in
to provide objective criteria of bowel viability.
azolium mucosal analysis correlated well with
ologic patterns of cellular destruction. It
rly showed the harmful effects of revasculariza-
on ischemically insulted mucosa. The mucosal
tudies revealed that the shifts merely reflected
act of revascularization and were of no value
viability index. Tetrazolium, although a re-
le index of mucosal damage, has limited clinical
ication because of the time required for analy-
Electromyography provides supportive evidence
urvival of the muscularis, whether intrinsic
soidal wave form or spike activity is found. The
ification of minor peristaltic activity in the
of spike waves is a new and easily interpre-
e guide to viability. Serosal pH has a limited
if taken separately. However, the combination of
rosal pH in a range of 7.35 to 7.85 with electro-
raphic evidence of muscularis survival supplies
eful parameter of viability. The finding of an
lotic pH of 7.95 to 8.40 in ischemically damaged
l, even in the presence of electromyographic ac-
ty, would suggest significant, probably pregan-
ous changes in that segment.

THE STATE OF THE SMALL INTESTINE MUCOSA
IN VARIOUS TERMS AFTER RADICAL OPERATIONS

SMALL INTESTINE

Malabsorption

3849 DETECTION OF DECONJUGATION OF BILE SALTS BY MEASUREMENT OF THE SPECIFIC ACTIVITY OF $^{14}CO_2$ IN EXPIRED AIR. *(E.)* Myerson, R. M.; Pineda, V. L.; Levison, M. E.; Rabinowitz, J. L. (VA Hosp., Philadelphia, Pa.). *Am. J. Med. Sci.* 267(1):35-39, 1974.

Bile acid deconjugation was assessed by measuring $^{14}CO_2$ specific activity of breath samples taken at intervals following p.o. administration of 1-^{14}C-glycocholic acid to 10 normal controls, 7 cirrhotics, 5 patients with steatorrhea unrelated to abnormalities of bile salt metabolism, 4 patients with stasis syndromes of the small bowel, 4 who had undergone ileal resection or bypass, and 10 with miscellaneous gastrointestinal disorders unassociated with steatorrhea. Marked increases in the $^{14}CO_2$ specific activity were observed in breath samples taken from all 4 patients with stasis syndromes and steatorrhea. These consisted of 3 patients with afferent loop syndrome following Billroth II gastroenterostomy and 1 with stasis and bacterial overgrowth secondary to scleroderma of the small intestine. Bacteriological examinations performed on jejunal contents from the patient with scleroderma showed 10^8 nonhemolytic *Escherichia coli*, 10^8 β-hemolytic *E. coli*, and 10^6 *Bacteroides melaningenicus*. Excessive bile salt deconjugation and steatorrhea were found in 3 patients who had underbone ileal resection or bypass for regional ileitis and in a

ent who developed a gastrocolic fistula after
ic ulcer surgery. Large numbers of *Bacteroides*
cultured from the stools and stomach contents
he latter patient. These results indicate that
th analysis is a rapid, simple, and safe method
detecting increased bile salt deconjugation and
be a valuable adjunct to investigation of pa-
ts with steatorrhea.

TROPICAL SPRUE IN SOUTH VIETNAM. *(E.)*
Miller, M. B.; Loftus, P. M.; Lohr, D. C.;
olds, R. D.; Bratton, J. L.; Hanson, J. P.; Keil,
. (12th USAF Hosp., Cam Ranh Bay, South Vietnam).
t. Med. 139(1):17-20, 1974.

clinical course, laboratory manifestations, and
lts of therapy of 12 cases of tropical sprue in
h Vietnam are presented. The diagnosis of
ical sprue was suspected whenever patients
ented with an insidious illness of nonbloody
rhea, characteristic stools, weight loss, and
al temperature. Many patients had gray-brown
tchy pigmentation of the skin, glossitis,
minal bloating, early satiety, anorexia,
ness and orthostatic hypotension. Weight loss
ed between 10 and 45 pounds, with a mean loss
7 pounds. Weight loss was related to duration
ymptoms before admission. All 12 patients
ially demonstrated abnormally low excretion to
lose, which ranged from 0.6 to 4.3 gm. A flat
ose tolerance test was found in 7 of 8 patients
ed. The small bowel series was definitely ab-
al in 8 of 10 patients studied. The charac-
stic X-ray small bowel findings have been as-
ed to atony of the bowel, characterized by the
ographic description of dilatation, segmentation,
mentation, flocculation, and moulage formation.
ncrease of neutral fat demonstrated by conven-
al fat stain on the stool was abnormal in all 12
ents tested. The average length of hospitali-
on for the 14 patients was 27 days. Four
ents failed to respond after 1 week of a gluten-
e diet. Four patients did not demonstrate a
atic response to therapy with folic acid alone,
subsequently responded within 3 days or less
n tetracycline was added.

THE EFFECT OF THERAPEUTIC IRRADIATION OF THE ABDOMEN ON INTESTINAL ABSORPTION IN
(E.) Sobo, A. O.; Johnston, I. D. A. (Dept.
otherap. Univ. Newcastle Upon Tyne, England).
J. Gastroenterol. 60(6):616-624, 1973.

effect of therapeutic irradiation on the absorp-
n of glucose, xylose, fat and Vitamin B_{12} was
lied in 12 male patients, 21 to 66 yr old with
ignant disease of the testis. Patients were
ated from the front and the back on alternate
s and a central dose of 150 rads was given daily.
total central dose during treatment was 3,000
s given over a period of 28 days. Glucose toler-
e at the end of treatment was reduced, but recov-
d 6 weeks later, indicating malabsorption. At
same time, the treated subjects showed decreased
e of urinary excretion of ingested vitamin B_{12}
incrased rate of fecal excretion of ingested fat. In contrast, urinary secretion of ingested xylose was not affected. One patient had severe diarrhea and excreted fecal fat at a rate of 58 gm/day towards the end of treatment. It is concluded that therapeutic irradiation affects the absorption of glucose, Vitamin B_{12} and fat but not of xylose, from the small intestine in man. The malabsorption observed after irradiation continued for some weeks and could explain in part the loss of weight associated with abdominal radiation in the absence of diarrhea.

3852 CALCIUM ABSORPTION FROM MILK AND LACTOSE-FREE MILK IN HEALTHY SUBJECTS AND PATIENTS WITH LACTOSE INTOLERANCE. *(E.)*
Kocian, J.; Skala, I.; Bakos, K. (Inst. Postgrad. Med. Training, Charles Univ., Prague, Czechoslovakia). *Digestion* 9(4):317-324, 1973.

By means of isotope ^{47}Ca, changes in the rate and intensity of calcium absorption from lactose-free and normal milk were investigated in healthy volunteers and in 11 patients (7 males and 4 females, aged 20-35 yr) with lactose intolerance. Fecal and urinary loss of ^{47}Ca and calcium retention were also studied. In healthy subjects the rate of absorption of calcium after ingestion of lactose-free milk was lower than that observed after ingestion of normal milk. In subjects with lactose intolerance, the opposite relationship was obtained. The total amount of absorbed and retained calcium did not differ significantly, regardless of whether calcium was administered in milk or in lactose-free milk. No significant differences were found in the utilization of calcium in subjects with lactose intolerance. In these patients the retardation of the peaks of the absorption curves after milk ingestion suggests a compensatory delay of gastric evacuation. The slower supply of chyme into the gut improves the calcium utilization in spite of relative lactase insufficiency. Well-tolerated lactose-free milk could be used to ensure a sufficient dietary supply of calcium in subjects with lactose intolerance. These results indicate that it would be advantageous to administer calcium in lactose-free milk and dairy products which are readily tolerated to milk-intolerant patients.

LARGE INTESTINE

3860 AN ULTRASTRUCTURAL STUDY OF THE LOCALIZATION OF THE CARCINOEMBRYONIC ANTIGEN IN ADENOCARCINOMAS OF THE HUMAN COLON. *(E.)* Huitric, E. (Ctr. Regional de Lutte contre le Cancer, Cedex, France). *Ann. Immunol. (Inst. Pasteur)* 124C(4):603-608, 1973.

An attempt was made to define the ultrastructural position of carcinoembryonic antigen (CEA) on the luminal surface of the tumoral cells lining neoplastic glands. Frozen 40 μ thick sections from surgically removed colonic tumors were incubated in turn in a rabbit antiserum directed against human colonic tumors, in sheep antirabbit peroxidase labeled antibody, and in 3-3' diaminobenzidine to reveal the peroxidase activity. Some sections were incubated in 3-3' diaminobenzidine alone. All controls incubated in normal rabbit serum were negative. However, some positive reactions were observed in the lumen of several tumoral glands. That reaction was also encountered in sections incubated in diaminobenzidine alone, and was assumed to be linked to a CEA specific marker. After the light microscopic examination, ultrathin sections (1 μ) with strong CEA activity were processed for electron microscopy. The sites of CEA activity appear as a continuous dense border lining the apical pole of the cells of the tumoral glands. A CEA positive reaction can also be seen on the outer lining of small circular bodies, measuring approximately 30 mμ in diameter, encountered along the outer leaflet of the apical membrane, around and between microvilli or along the cytoplasmic projections. CEA seems to be localized in the outer leaflet of the apical membrane of tumoral cells, more precisely, in the glycoprotein coating of these cells. The close association of CEA with the cell coat may account for the variations observed optically in the intensity of the CEA reaction. In the tumoral glands, where the apical border of the cells is frequently very altered, the intensity of the CEA reaction will reflect the state of the apical pole of tumoral cells. No CEA was seen with an intracellular localization, neither at the light nor at the electron microscopic level.

3861 MALIGNANT ANORECTAL MELANOMAS. *(Fr.)* Huguier, M.; Luboinski, J. (Rothschild Hosp., Paris, France). *Arch. Fr. Mal. App. Dig.* 62(7):579-590, 1973.

The diagnosis, treatment, and prognosis are considered for 17 patients (12 women and 5 men, aged 38-74 yr) with malignant melanomas of the anorectum (16 cases) or rectum (1). The lesion simulated complicated hemorrhoids in 4 cases and anorectal suppuration in 1. Mucosa covering the lesion was not ulcerated in 4 cases, and the tumor was pedunculated in 3. One patient had 2 tumors. Pigmentation was present in 9 of these 17 cases. Lesions ranged in size from 1 to more than 10 cm. Three patients presented with signs of dissemination: melanuria (1), cervical adenopathy (1), and hepatic and pulmonary metastases, bilateral inguinocrural adenopathy, and a pigmented nodule on the thorax (1). Errors in diagnosis were initially made in 3 cases because of difficulties in distinguishing unpigmented melanomas from undifferentiated carcinomas or adenocarcinomas and fibroblastic sarcomas. Abdom inal perineal resections were performed in 6 patient and local excision of the tumor on 6 others. Four patients received radiotherapy and 1 was given chemo therapy. Signs of metastases eventually developed in 16 of these patients. Eleven patients died 1-50 months after institution of treatment, and 4 patient are still alive after 36-48 months. Survivals of more than 1.5 yr were obtained in 2 patients by removal of local recurrences.

3862 MALAKOPLAKIA: PATHOGENESIS AND ULTRASTRUC TURAL MORPHOGENESIS: A PROBLEM OF ALTERED MACROPHAGE (PHAGOLYSOSOMAL) RESPONSE. *(E.)* Lou, T.

Teplitz, C. (Rhode Island Hosp., Providence).
Pathol. 5(2):191-207, 1974.

ttempt was made to trace the ultrastructural
hogenesis of malakoplakia with specific emphasis
lucidating the various developmental stages in
formation of the pathognomonic calcific laminated
usions (Michaelis-Gutmann bodies) in the charac-
stic "von Hansemann histiocytes." The etiologic
ts in the pathogenesis of the colonic malakopla-
lesion studied were ultrastructurally and bac-
ologically identified as coliform bacteria (*E.*
and Klebsiella). Intact bacilli were first
ent in macrophagic phagosomes. Bacteria in var-
states of morphologic integrity were then found
in coalescent and progressively enlarging phago-
somes. Giant phagolysosomal bodies then showed de-
rative change of both matrix and limiting mem-
es in otherwise ultrastructurally intact macro-
es. Finally, the deposition of calcium crystals
in these large phagolysosomes led to the develop-
of the characteristic concentrically laminated,
stage Michaelis-Gutmann inclusions. The morpho-
c features of colonic malakoplakia are identical
he more commonly occurring genitourinary form,
a review of the accumulated data suggests that,
rdless of site, the morphogenesis and pathogene-
of malakoplakia may well be the same. The ultra-
ctural demonstration of an unusual metamorphosis
hagolysosomes within macrophages, plus the over-
available information in the literature, suggests
malakoplakia probably represents a morphologic
festation of altered host macrophage response,
that gram negative enteric bacilli may be the
common specific etiologic agent. In the light
oscopic prediagnostic stage, the earliest or
mal pathologic criterion for the diagnosis of
koplakia is the ultrastructural identification of
negative bacilli or their remnants among very
e macrophagic lysosomes showing early evidence of
ium phosphate deposition.

COLON CANCER AND BLOOD-CHOLESTEROL. *(E.)*
Rose, G.; Blackburn, H.; Keys, A.; Taylor,
.; Kannel, W. B.; Paul, O.; Reid, D. D.; Stam-
J. (St. Mary's Hosp. Med. Sch., London, England).
et 1(7850):181-183, 1974.

rnationally, there is a correlation between mortal-
rates for colonic cancer and coronary heart dis-
, with dietary fat being suspected as a common
logical factor. Thus, it is hypothesized that
in a population, the levels of blood cholesterol
dietary fat should predict the risk of colonic
er. Pooled data from 6 studies of coronary
t disease in men yielded 90 cases of fatal colon
er. In 57 of these cases, the initial blood
esterol value was below the expected value, the
deviation of the standardized scores being
3 (corresponding to 5-7 mg/100 ml) and the median
ation being -0.26 (10-13 mg/100 ml). This ten-
y was not significantly correlated with the in-
al from screening to death, nor was it seen in
s involving other alimentary carcinomas. The
ency to low blood cholesterol levels in the co-
c cancer patients was significant at the 5%
l.

PANCREAS

3919 PANCREATIC ABSCESS. *(E.)* Miller, T. A.; Lindenauer, M.; Frey, C. F.; Stanley, J. C. (Univ. Michigan Med. Ctr., Ann Arbor). *Arch. Surg.* 108(4):545-551, 1974.

Pancreatic abscesses were studied in 63 patients (47 males and 16 females, aged 18-77 yr) who were seen at the University of Michigan Medical Center from 1936 to 1972. Acute pancreatitis preceded abscess formation in 61 cases. Carcinoma of the ampulla of Vater and a posterior penetrating ulcer of the third portion of the duodenum in a patient with a Zollinger-Ellison tumor antedated abscess development in the remaining 2. Associated conditions included postoperative pancreatitis in 30, biliary tract disease in 17, alcoholism in 15. Bleeding complications affected 26 patients, 12 of whom died. Renal failure was encountered in 22, 19 of whom died. The mortality of the overall series was 53.9%. No patient survived without surgical intervention. The mortality following operative incision and drainage was 37%. Limited success following surgical therapy was attributed partly to delays in the diagnosis of pancreatic abscess. Clinical evidence of abscess was present in 85% of these patients. Two clinical patterns emerged during this series. First, in instances of severe pancreatitis with marked abdominal distention, hypotension and hypocalcemia, vigorous, aggressive supportive therapy often failed. Second, patients with acute pancreatitis responded well to conservative therapy but pancreatitis recurred within 10 days to 3 weeks later. Attention to clinical signs and symptoms and a high index of suspicion should allow for earlier operative drainage and improved patient survival. The importance of roentgenographic examination in confirming this diagnosis is stressed. The presence of gas bubbles within the abscess cavity on abdominal plain film gives strong support to this diagnosis. It is suggested that ultrasonography represents a significant development in the diagnosis of pancreatic abscess.

3920 MANAGEMENT OF THE PANCREAS AFTER PANCREATICODUODENECTOMY. *(E.)* Aston, S. J.; Longmire, Jr., W. P. (Univ. California Med. Sch., Los Angeles). *Ann. Surg.* 179(3):322-327, 1974.

A review was made of 65 patients (aged 3-84 yr) who had undergone pancreaticoduodenectomy in an effort to compare the different modes of management employe in their postoperative periods. Of the 65, carcinom of the head of the pancreas was diagnosed in 39, carcinoma of the ampulla of Vater in 16, and carcinoma of the distal common bile duct in 16. In 10 patient the continuity of the gastrointestinal tract was reconstructed by anastomosis of a large dilated pancreatic duct directly to the mucosa of the jejunum. In 5 patients with a small pancreatic duct, duct-to-mucosa anastomosis was also performed. In 38 patients pancreaticojejunostomy was performed end-to-end so that the cut end of the pancreas was invagina ed into the end of the jejunum. The anastomosis was performed between the capsule of the pancreas and th serosal surface of the jejunum. In 5 patients with a small pancreatic duct, the transected end of the pancreas was buried into an opening in the side of t jejunum with the bowel wall sewn down to the pancrea in two layers. The pancreatic duct was ligated and the transected end of the pancreas oversewn with interrupted sutures in 4 patients. In the final 3 patients, the entire pancreas was removed at the tim of pancreaticuduodenectomy. In this series pancreat fistulae were associated with 4 of the 9 operative deaths and were the most common cause of postoperative morbidity. In those undergoing pancreaticoduodenectomy with partial pancreatectomy, fewer postoperative problems occurred with a direct anastomosi between the pancreatic duct and mucosa of the jejunu When there is a large dilated pancreatic duct and a good duct-to-mucosa anastomosis can be obtained with the jejunum, this type of reconstruction is mos desirable. Total pancreatectomy is suggested for patients with multiple tumor nodules or a mass in

head of the pancreas with marked induration of the
creas distally, preventing localization of the
or. This procedure, however, does add the concern
permanent diabetic management to the postoperative
e.

PANCREAS

Pancreatitis

1 HYPOTHERMIA, THROMBOSIS, AND ACUTE PAN-
CREATITIS. *(E.)* Savides, E. P.; Hoff-
nd, B. I. (Whittington Hosp., London, England).
Med. J. 1(5908):614, 1974.

ase of fatal hypothermia with acute pancreatitis
which pancreatic venous thrombosis occurred in
upper superior pancreatic duodenal vein and its
rapancreatic branches is reported. The patient,
5-yr-old woman, was admitted to the hospital
a state of confusion; her condition had been de-
iorating over a period of 4 months. In this pa-
nt, the thrombosis of the upper superior pancre-
coduodenal vein and its intrapancreatic branches
have been responsible for the pancreatitis ra-
r than secondary to it.

2 ACUTE PANCREATITIS SECONDARY TO CALCIUM
INFUSION IN A DIALYSIS PATIENT. *(E.)*
hgelerent, E. L.; David, D. S. (St. Luke's Hosp.
Ctr., New York, N.Y.). *Arch. Surg.* 108(2):218-219, 1974.

A 58-yr-old man with chronic end-stage renal disease secondary to severe hypertension and gout with renal lithiasis was placed on chronic hemodialysis. Several months later, the patient underwent an i.v. calcium infusion test to evaluate his parathyroid gland function; he received 15 mg/kg elemental calcium in the form of gluconate calcium in 5% dextrose in water. During the second hour of the test, the patient vomited spontaneously. Four hours after completion of the test, the patient complained of cramping upper abdominal pain that persisted and became more severe and penetrated to the back during the next 24 hr. This episode of acute pancreatitis was undoubtedly precipitated by the calcium infusion with subsequent hypercalcemia. It is expected that acute pancreatitis will be seen more frequently with increasing use of the calcium infusion test in patients with renal failure. Because of the high instance of morbidity and mortality associated with pancreatitis in the general population, the calcium infusion test should be performed with caution in uremic patients whose serum calcium levels are high normal. The dose of calcium given might also be decreased in these patients, and the test should be discontinued at the first sign of gastrointestinal distress.

3933 ACUTE PANCREATITIS SECONDARY TO IATROGENIC HYPERCALCEMIA: IMPLICATIONS OF HYPERALIMENTATION.

(E.) Manson, R. R. (Carle Fdn. Hosp., Urbana, Ill.). *Arch. Surg.* 108(2):213-215, 1974.

A 49-yr-old woman with a history of an enterocutaneous fistula which developed after a total abdominal hysterectomy and lysis of adhesions was placed on a regimen of 2 U/day of a hyperalimentation solution. Magnesium sulfate, gluceptatate calcium, sodium chloride, potassium chloride, potassium phosphate, and a multivitamin mixture were added to the solution. At various times throughout the next several months, hyperalimentation was discontinued; however, the regimen was reinstated each time because of nausea and continuous vomiting. After a period of months, the patient suffered an episode of acute pancreatitis, which occurred as a complication of hypercalcemia secondary to the calcium infusion. There is some evidence that hypercalcemia in itself may activate trypsinogen to trypsin causing pancreatitis. While calcium alone does not appear to activate pancreatic trypsinogen, in the presence of a small amount of trypsin, an increasing calcium ion concentration will permit the activation of a larger amount of trypsinogen to trypsin. This is believed to be the first report of pancreatitis secondary to acute hypercalcemia produced by chronic calcium intake as part of the hyperalimentation infusion.

3934 CHANGING METHODS IN THE TREATMENT OF SEVERE PANCREATITIS.

(E.) Feller, J. H.; Brown, R. A.; MacLaren Toussaint, G. P.; Thompson, A. G. (McGill Univ. Surg. Clin., Montreal, Canada). *Am. J. Surg.* 127(2):196-201, 1974.

A review was made of 200 patients with acute pancreatitis diagnosed by (1) a serum amylase level below 600 Somogyi units with typical clinical findings plus an elevated serum lipase or urinary amylase level or depressed serum calcium level; or (2) a serum amylase level above 600 Somogyi units with supportive clinical findings. Of these 200 cases, 83 were considered to have serious disease, in some of whom the serious nature of their states had not been initially recognized and therefore treatment directed against the development of major complications was not immediately started. It is noted that, in general, serum amylase levels did not relate directly to the severity of the disease. However, higher levels of amylase indicated mild pancreatitis or the presence of a pseudocyst. Serum calcium levels, however, proved valuable in both the initial evaluation of the patient's condition and the day to day response to therapy. Major complications encountered in this series included: nutritional depletion (83), abscess or acute pseudocysts (15), respiratory failure (18), and gross upper gastrointestinal bleeding (16). Treatment must be directed toward prevention of these complications if the patients are to survive. It is suggested that intravenous hyperalimentation be started as soon as possible. The use of an elemental type diet for means of nutritional support is employed as a sequel to the primary phase of i.v. hyperalimentatio For the complications of abscess or acute pseudocyst, simple external drainage is recommended. It i suggested that ultrasonic B scanning of the pancreas be used to detect the presence of fluid collections, and to determine with accuracy any change in size, thus aiding in the decision as to whether or not operative drainage is indicated. Peritoneal irrigation is extremely useful in the management of these complications in that patients improve when toxic material is washed out of the peritoneal cavity. Indications for operation in acute pancreatitis are: difficulty in diagnosis, deterioration in the patient's condition, and suspected pancreatic abscess or pseudocyst. Acute respiratory failure occurred as a complication in 18 patients and contributed to the death of 8 of these 18. Upper gastrointestinal bleeding occurred in 16 patients and responded in all but 1 case to treatment consisting of transfusions of whole blood as indicated and cold saline irrigation of the stomach at the site of bleeding. Early feeding of the elemental diet via a nasogastric tube may reduce the change of gastric mucosal hemorrhage.

3935 ACUTE HEMORRHAGIC PANCREATITIS IN THE DOG. I. THE ACTION OF BILE.

(E.) Schapiro, H. Britt, L. G.; Blackwell, C. F.; Gaines, K. J. (Univ. Tennessee Med. Units, Memphis). *Arch. Surg.* 107(4): 608-612, 1973.

Acute hemorrhagic pancreatitis was produced in 31 mongrel dogs by the closed-loop technique. In 14 of these dogs, bile was excluded from the duodenal loop while in the remaining 17, bile was allowed to enter the loop. The presence of bile in the closed duodenal loop seemed to increase the morbidity of the experimentally induced pancreatitis and to increase the rate of elevation in the serum alkaline phosphatase, LDH, and serum lipase levels. Pancreatic acinar tissue disruption appeared after 9 hr in the dogs with bile emptying into the closed loops and after 12 hr in the dogs with bile excluded. The presence of bile in the closed loop also increased the peritoneal fluid amylase concentrations, so that after 24 hr they were nearly twice as high as in the bile excluded dogs. The reflux of the duodenal contents into the pancreatic duct system may be the primary cause for the observed pancreatitis, and the addition of bile may serve as a catalyst to hasten the process.

3936 TRANSIENT HYPERTENSION WITH ACUTE PANCREATITIS.

(E.) Sankaran, S.; Lucas, C. E.; Walt, A. J. (Wayne State Univ. Sch. Med., Detroit, Mich.). *Surg. Gynecol. Obstet.* 138(2):235-238, 1974

The association of hypertension and pancreatitis has

n studied in 42 patients (33 males and 9 females,
n age 41 yr) with acute alcoholic pancreatitis.
3 cases there was a past history of hypertension,
none of these 3 patients had received antihyper-
sive medications. No antihypertensive medica-
ns were used during the course of treatment in
current hospitalization. Of the 42 patients,
developed transient hypertension during the acute
se of pancreatitis, i.e., the phase manifested
abdominal pain, tenderness, fever, leukocytosis,
hyperamylasemia. Their systolic pressures during
s phase ranged from 230 to 116 mm mercury; dias-
ic ranged from 160 to 60 mm. In 2 patients visual
turbances developed, apparently related to the
ertension they experienced, which cleared with
rovement of the pancreatitis. Of these 42 pa-
nts, 17 had been admitted prior to the present
dy for acute pancreatitis and all of them demon-
ated transient hypertension during the acute
se. These results indicate that the association
ween acute pancreatitis and transient hypertension
ears to be real. The 95% incidence of hyperten-
n during the acute phase of pancreatitis is sig-
icantly high. The clinical significance of tran-
nt hypertension with acute pancreatitis is not
ar. The blood pressure returned to normal in most
ients with improvement in the clinical status and
urn of the serum amylase level to normal. It was
t that the electrocardiographic findings may have
n related to previous hypotension or hypoxia, elec-
lyte imbalance, the effects of pain on the coron-
circulation, or circulating peptides. The
se of this associated hypertension also is un-
ar. It is suggested that the central nervous
tem lesions are a more important etiological fac-
in these patients than the pain they experience.
ohol, though a factor in the history of each of
se patients, did not likely cause the hyperten-
n, for hypertension persisted in these patients
er alcohol and its metabolites would have been
pletely eliminated from the body. None of the
ients in this series exhibited signs of respira-
y insufficiency. Fluid overload also did not
ear to be the cause of hypertension in these pat-
ts. It is suggested that transient hypertension in
se patients indicates the presence of circulating
oconstrictor substances in patients with acute alco-
ic pancreatitis.

7 RENAL VASOCONSTRICTION IN ASSOCIATION
WITH ACUTE PANCREATITIS. *(E.)* Werner, M.
Hayes, D. F.; Lucas, C. E.; Rosenberg, I. K.
yne State Univ. Sch. Med., Detroit, Mich.).
J. Surg. 127(2):185-190, 1974.

al function was evaluated in 11 patients in the
te phase of alcoholic pancreatitis and again
ing convalescence in 7 of these patients. Average
merular filtration rate, effective renal plasma
v, and true renal plasma flow were decreased
the acute phase. Osmolar clearance, amylase clear-
e, mean arterial blood pressure, renal vascular
istance, and total peripheral resistance rose in
acute phase. All parameters returned toward
mal with convalescence. These findings suggest
elease of a vasopressor during the acute phase of
creatitis. In one patient receiving a phentolamine infusion, improvement in systemic hemodynamics was apparent and the increase in urine volume suggested improved renal function. A marked reduction in both the true renal blood flow and the renal fraction of the cardiac output occurred. This indicated that the infusion had impaired the renal circulation and might have been deleterious if continued for a prolonged period. It is suggested that a direct infusion of the vasodilator into the renal arteries would have provided improvement in renal hemodynamics.

3938 IMPLICATIONS OF DIAGNOSTIC ULTRASOUND IN THE SURGICAL MANAGEMENT OF PANCREATIC PSEUDOCYSTS. *(E.)* Bradley, III., E. L.; Clements, Jr., J. L. (Emory Univ. Sch. Med., Atlanta, Ga.). *Am. J. Surg.* 127(2):163-173, 1974.

A group of 25 consecutive patients (5 females and 20 males, aged 12-64 yr) with a clinical diagnosis of pancreatic pseudocyst supported by history, abdominal mass or fullness, elevated serum amylase level, and confirmatory upper gastrointestinal series underwent preoperative examination by ultrasound. On 13 occasions the ultrasonic configuration of a cyst was present in agreement with the clinical impression. Subsequent exploration or autopsy confirmed the cyst in 10 instances, with the remaining patients not coming to exploration. However, in 13 other cases, solid tissue was predicted by ultrasound, not by clinical impression. Of these 13, 9 patients came to exploration or autopsy, and the ultrasound diagnosis was confirmed in 8, in each of whom the mass consisted of peripancreatic edema. This diagnostic method thereby avoids unnecessary exploration in these patients. It is noted, however, that if a cystic mass is closely adherent to the abdominal wall, ultrasound will still describe the cystic nature of the mass, but that separation of the cyst wall echoes from those resulting from normal abdominal wall structures may not be possible. It is also cautioned that, since cyst demonstration does not contain any histologic information, i.v. pyelograms as well as cholecystograms should be obtained in all patients when the mass presents in the right upper quadrant.

LIVER AND BILIARY TRACT

3953 INFECTIOUS MONONUCLEOSIS IN CHILDREN: DIAGNOSTIC PROBLEMS DEALING WITH LIVER INVOLVEMENT. *(Ger.)* Peley, I.; Kadas, I.; Varga, L.; Labady, M. (Munic. Hosp., Pecs, Hungary). *Acta Paediatr. Acad. Sci. Hung.* 14(2):145-149, 1973.

Of 105 children with infectious mononucleosis, 93 had hepatosplenomegaly, 6 had hepatomegaly, 1 had splenomegaly, and 51 had abnormal liver function tests in addition to the characteristic symptoms of this disease. Liver function tests included thymol turbidity and serum transaminase activities and, in most cases, the BSP test and urine examination. In some cases the diagnosis had to be established indirectly by liver function tests and biopsy findings since the Paul-Bunnell reaction was positive in few of the children. This test was positive in only 3 of 54 children with normal liver function, in 1/5 of those with abnormal liver function, and in 4 of 16 patients who had pronounced hepatomegaly or jaundice. The higher percentage of positive Paul-Bunnell tests among children with abnormal liver function may be explained by (1) an erroneous diagnosis of infectious mononucleosis in those with less severe symptoms, (2) the relative insensitivity of the Paul-Bunnell test, or (3) this test may not necessarily be positive in children with infectious mononucleosis. Liver function tests normalized rapidly and the spleen and liver returned to their normal size in 14-21 days although in some patients they were palpable even after several months. Biopsies performed on the 16 patients with pronounced hepatomegaly or jaundice revealed marked inflammatory infiltration of lymphoid cells and, in contrast to viral hepatitis, an intact hepatic parenchyma; pronounced activity of Kupffer's cells was observed. These changes are similar to those found in adults with infectious mononucleosis.

3954 REYE'S SYNDROME: CLINICAL DIAGNOSIS AND TREATMENT WITH PERITONEAL DIALYSIS. *(E.)* Samaha, F. J.; Blau, E.; Berardinelli, J. L. (Univ. Pittsburgh Sch. Med., Pa.). *Pediatrics* 53(3):336-340, 1974.

Of 24 children with Reye's syndrome, each patient diagnosed as having acute hepatic encephalopathy was subjected to an hepatic coma regimen: glucose infusions were given in appropriate concentrations to

ntain the blood glucose at homeostatic levels.
addition, neomycin (100/mg/kg/day), saline enemas,
adrenal corticosteroid therapy (0.5-1.0 mg/kg/
dexamethasone) were administered. Of 11 patients
were also treated with peritoneal dialysis, 9
ed. Two of the 13 patients treated only with the
atic coma regimen lived. The data suggest that
n used before evidence of irreversible brain
m damage, peritoneal dialysis may offer hope in
ersing the high mortality of Reye's syndrome. Of
24 cases observed, there was good correlation
ween the typical clinical presentation with ab-
mal prothrombin time, SGOT, SGPT, and blood am-
ia levels and the abnormal liver histology des-
bed in Reye's syndrome. Thus, a medical history
routine laboratory data are all that is neces-
to recognize the syndrome.

5 SERUM ALPHA-FETOPROTEIN AND Ga^{67} CITRATE UPTAKE IN HEPATOMA.

(E.) Suzuki, T.;
sumoto, Y.; Manabe, T.; Honjo, I.; Hamamoto, K.;
zuka, K. (Kyoto Univ. Med. Sch., Japan). *Am.*
Roentgenol. Radium Ther. Nucl. Med. 120(3):
-633, 1974.

m α-fetoprotein (AFP) was assayed by the Ouchter-
and Mancini methods in 71 patients with liver
cinomas (27 hepatomas, 5 cholangiomas, and 39
static carcinomas of the liver); these patients
also subjected to scintiphotography with ^{67}Ga
ate. Serum AFP was detected in 17 patients with
toma. The hepatoma patients also showed in-
sed ^{67}Ga citrate uptake, this increase being
ter in the AFP-negative cases than in the AFP-
tive cases. ^{67}Ga uptake was not great in most
he patients with cholangioma or metastatic car-
mas of the liver, although uptake of the iso-
was increased in 2 of the latter cases. The
ee of ^{67}Ga concentration did not differ in he-
mas from cirrhotic and noncirrhotic livers.
, scintiphotography with ^{67}Ga citrate appears
e a useful screening method for hepatomas which
ot be identified by the AFP test.

LIVER GLYCOGEN IN MAN - THE EFFECT OF TOTAL STARVATION OR A CARBOHYDRATE-POOR FOLLOWED BY CARBOHYDRATE REFEEDING.

(E.)
son, Jr., L. H.; Hultman, E. (St. Eriks Hosp.,
kholm, Sweden). *Scand. J. Clin. Lab. Invest.*
):325-330, 1973.

teen healthy young human subjects were subjec-
to short-term (12-14 hr) or prolonged (1-3 days)
vation or were fed a carbohydrate-poor diet
owed by a carbohydrate-rich diet. Liver glyco-
was measured in specimens obtained by repeated
utaneous biopsies during this period. During
and following an overnight fast, there was a
decrease of about 0.30 mmol glucosyl U/kg wet
r tissue/min in the liver glycogen content dur-
4 hr further starvation. Prolonged starvation
aintenance on a carbohydrate-poor normocaloric
decreased the liver glycogen from a mean of
to 24-55 mmol glycosyl U/kg within 24 hr. During
dditional period of up to 9 days on the carbo-
ate-poor diet, the liver glycogen remained at
a low level. Refeeding with a carbohydrate-rich diet resulted in a rapid increase in liver glycogen to values exceeding the basal level (424-624 mmol glucosyl U/kg wet liver tissue).

3957 REYE SYNDROME. AN ASSOCIATION WITH TYPE 1 VACCINE-LIKE POLIOVIRUS.

(E.) Brunberg, J. A.; Bell, W. E. (David Grant Med. Ctr., Travis Air Force Base, Calif.). *Arch. Neurol.* 30(4):304-306, 1974.

Polio type 1 vaccine-like virus was isolated from the spinal fluid, ileum, and brain tissue of a 7-yr-old girl whose clinical course and postmortem findings indicated Reye syndrome. Her clinical history revealed previous immunization with seven courses of inactivated polio vaccine and close contact, 3 weeks prior to the onset of her illness, with a child recently immunized with oral trivalent attenuated poliovirus. The data suggest a causal relation between poliovirus infection and the patient's clinical illness, although it is possible that exposure to a recently immunized individual was followed by intestinal poliovirus colonization and subsequent dissemination of virus due to altered host resistance during the course of an independent disease. The patient's illness may have represented a complication of "contact" polio immunization. The data indicate that Reye syndrome is a nonspecific multisystemic response to a variety of agents.

3958 SAVINGS THROUGH THE DIRECT APPROACH TO JAUNDICE.

(E.) Del Guercio, L. R. M.; Mehta, M.; Kline, R.; Kuzmak, L.; Mattey, W. (St. Barnabas Med. Ctr., Livingston, N.J.). *Am. J. Surg.* 127(2):157-162, 1974.

The clinical and fiscal hospital records of 60 consecutive patients who underwent minilaparotomy for jaundice were analyzed for end results and cost effectiveness. The various diagnostic manipulations are performed through a 6-cm upper midline incision with the patient under local anesthesia. The procedure is carried out in an x-ray angiography room, and involves transhepatic cholangiography, liver biopsy, bile analysis, portal manometry, and omentoportography. This direct approach to jaundice is reserved for patients in whom the diagnosis is uncertain because of an atypical clinical course or confusing laboratory findings. When surgical jaundice is strongly suspected, the procedure is used preoperatively to assess the number and locations of stones, the extent of tumor invasion, and the degree of sphincteric spasm or stenosis. Among the 60 patients who underwent minilaparotomy, there were no mortalities, no need for blood transfusion, no evidence of bile leakage, and no episodes of septicemia. The procedure avoided formal laparotomy under general anesthesia in 48% of the patients. The exact tissue diagnosis was established in 62% of the patients in whom diseased tissue was present, and the anatomic diagnosis was made in 97% of the 60 patients. Hospital charges totaled \$95.00. The average savings that could have been achieved if the procedure had been carried out as soon as indicated was \$984.00.

3959 PLASMA AMINO ACIDS IN PATIENTS WITH HEPATIC ENCEPHALOPATHY: EFFECTS OF AMINO ACID INFUSIONS. *(E.)* Fischer, J. E.; Yoshimura, N.; Aguirre, A.; James, J. H.; Cummings, M. G.; Abel, R. M.; Deindoerfer, F. (Massachusetts Gen. Hosp., Boston). *Am. J. Surg.* 127(1):40-47, 1974.

The plasma amino acid patterns were studied in patients with advanced liver disease on protein-restricted diets or on hyperalimentation. In those patients on a protein-restricted diet, hepatic encephalopathy invariably occurred when the diet contained 40 g or more of protein; when protein was restricted to 20 or 25 g, the hepatic encephalopathy improved markedly. Infusions with amino acid solutions at rates greater than 45 to 50 g protein/24 hr were generally associated with a marked increase in hepatic encephalopathy without diminished hepatic function. In patients on protein-restricted diets, the amino acid patterns reflected excessive phenylalanine and methionine, mildly elevated tryptophan, lysine, glutamic acid, aspartic acid, ornithine, glycine, tyrosine, and serine, and decreased leucine, isoleucine, and valine. Infusions with essential amino acids failed to increase the persistently low concentrations of the branched chain essential amino acids, although phenylalanine and methionine were greatly elevated; the concentrations of many of the nonessential amino acids were reduced. Similar results were obtained following infusions of essential and nonessential amino acids, except that most nonessential amino acids remained highly elevated. Thus, patients with severe hepatic impairment appear to be generally incapable of utilizing phenylalanine and methionine. The deficient utilization of plasma phenylalanine may be detrimental to the patient with hepatic encephalopathy and coma.

3960 CLINICAL MANIFESTATIONS OF HEPATOMA. A REVIEW OF 6 YEARS' EXPERIENCE AT A CANCER HOSPITAL. *(E.)* Ihde, D. C.; Sherlock, P.; Winawer, S. J.; Fortner, J. G. (Mem. Sloan-Kettering Cancer Ctr., New York, N.Y.). *Am. J. Med.* 56(1):83-91, 1974.

Of 67 adults with histologically documented hepatocellular carcinoma, more than 70% presented with abdominal pain, right upper quadrant mass, and weight loss or ascites. Among the remainder, symptoms were suggestive of cholecystitis, deterioration in hepatocellular function, progressive pulmonary tumor, pathologic fracture of metastatic bone lesions, obstructive jaundice with pruritus, and chronic hepatitis. By the time of referral, nearly all patients showed evidence of single or multiple large intrahepatic masses detectable by physical examination, isotopic liver scan, or celiac arteriography. Alphafetoglobulin was present in 36% of the serum samples, while hepatitis-associated antigen was detected in none. Survival was brief among patients who could not be subjected to hepatic lobectomy, and death occurred among over 1/2 of the patients during the first hospital admission. Cirrhosis was observed in 69% of patients with adequate pathologic examination. Autopsies revealed extensive metastatic disease, primarily in the lungs, intraabdominal lymph nodes, adrenal glands, great veins adjacent to the liver, diaphragm, and skeleton. Tumor distribution most commonly involved the right and left liver lobes, the left lobe rarely being involved by itself. A second malignant neoplasm was documented in about 1/8 of the patients, and a few patients showed evidence of a variety of paraneoplastic syndromes. Death was most frequently due to hepatocellular failure, sepsis, or massive gastrointestinal bleeding.

3961 CLINICAL IMPLICATIONS OF MONOCLONAL GAMMOPATHY IN CHRONIC LIVER DISEASE. *(E.)* Slavin, S.; Zlotnick, A.; Levij, I. S.; Eliakim, M. (Hadassah Univ. Hosp., Jerusalem, Israel). *Digestive Dis.* 19(3):223-234, 1974.

An association between chronic liver disease and monoclonal gammopathy is described in 4 patients with chronic aggressive hepatitis progressing to cirrhosis, 2 with cryptogenic cirrhosis, and 1 with cholangiohepatitis. Three cases had cold precipitable IgG-IgM complexes; two of them manifested a syndrome of ulcerative purpura, Raynaud's phenomena, arthritis, neuropathy, encephalopathy, myopathy, and terminal glomerulonephritis. Two additional cases had occasional purpura, and in two other cases the gammopathy was asymptomatic. In one patient, monoclonal gammopathy developed from polyclonal gammopathy during the course of the disease, and transition to malignant lymphoma occurred several months later. Prednisone, ACTH, and azathioprine had no appreciable effect on the cryoglobulinemia. Two patients died of major vascular occlusions and glomerulonephritis 4 and 6 yr after onset of purpura; 2 other patients died of complications of liver disease (1 probably of hepatoma). In two cases, the monoclonal fraction disappeared or decreased with prednisone alone and prednisone and chlorambucil, respectively. It is possible that the presence of paraproteinemia in liver disease may not only precede the appearance of multiple myeloma or lymphosarcoma, it may also signal the development of hepatoma.

3962 GLYCOGEN STORAGE DISEASE TYPE IX: BENIGN GLYCOGENOSIS OF LIVER AND HEPATIC PHOSPHORYLASE KINASE DEFICIENCY. *(E.)* Schimke, R. N.; Zakheim, R. M.; Corder, R. C.; Hug, G. (Kansas Univ. Med. Sch., Kansas City). *J. Pediatr.* 83(6):1031-1034, 1973.

Case reports are presented on two male patients with glycogen storage disease type IX; the mothers of thes patients were sibs, indicating an X-linked inheritanc Examination of liver biopsy specimens from these patients indicated that the liver glycogen concentration was increased, while the liver phosphorylase activity was less than 10% normal. Total liver phosphorylase was normal, indicating that the low phosphorylase activity was not a result of phosphorylase deficiency. It was, rather, the result of diminished liver phosphorylase kinase activity. The addition of adenosine triphosphate and magnesium chloride to the patients' liver homogenates did not activate phosphorylase as it did in normal controls.

ivation of endogenous phosphorylase did occur with
further addition of purified kinase to the liver
ogenates. All other biochemical parameters were
mal. Glycogen concentration and phosphorylase
phosphorylase kinase activities in muscle speci-
s were normal, indicating that this X-linked form
glycogen storage disease type IX is not a gener-
zed disorder.

3 LIVER SNAPS AND THE DETECTION OF CLINICALLY
UNSUSPECTED LIVER METASTASES. *(E.)* Davies,
J.; Vernon, M.; Croft, D. N. (St. Thomas' Hosp.,
lon, England). *Lancet* 7852:279-280, 1974.

letermine the value of radioisotope liver imaging
the preoperative assessment of patients with
table cancer, liver images were obtained in 46
ients with carcinoma of the large bowel who did
have hepatomegaly. At operation or necropsy, 8
) were proved to have hepatic secondaries, and
er snaps produced by a gamma camera detected 7 of
e. The technique gave a correct answer in 44
ients, giving an overall accuracy of 95%. This
lence implies that liver imaging is useful in
preoperative assessment of patients with cancer,
if the liver is clinically normal. Of the 8
ients with liver metastases, 7 were dead within
nonths of operation, while over the same time
iod only 2 of those without liver secondaries died.

ULTRASTRUCTURAL FINDINGS WITH OSMIUM IM-
PREGNATION IN THE HUMAN LIVER DURING
ESTASIS. *(It.)* Barone, P.; Inferrera, C.;
ozza, G. (Inst. Anat. Pathol. Histol., Univ.
ina, Italy). *Boll. Soc. Ital. Biol. Sper.*
2):874-875, 1972.

ions of human liver from patients with chole-
is were stained with osmium by the technique of
nd and Murray and were examined by light and
tron microscopy. Under the light microscope a
ction was found in the number and area of Golgi
ratuses. An osmiophilic material, which was in-
reted to be bile, was present in bile capil-
es and the hepatocyte cytoplasm. Under the
tron microscope, intensely osmiophilic bile
mbi and fine osmiophilic granules were found in
ted bile capillaries. Large numbers of osmio-
ic granules were present in the endoplasmic re-
lum which was also greatly dilated. Changes in
Golgi apparatus consisted of accumulations of
k granules in the cisternae and vesicles on its
r side, but these granules were normal or only
htly osmiophilic. A reduction was observed
he osmiophilic area of the formative side. This
associated with distortion and fragmentation of
vesicles. Vesicles originating from the endo-
m or Golgi apparatus were filled with granular
rial and appeared to develop on the sinusoidal
of the cell since similar granular material was
d in Disse's spaces and/or in the cytoplasm of
vated Kupffer's cells. These findings suggest
bile, both inside and outside the hepatocyte,
s a positive test with osmium and that this
nique can be used to identify fine granules of
which cannot be detected by other methods.

3965 DIAGNOSIS OF GLYCOGEN STORAGE DISEASE TYPE I BY SERUM IMMUNODIFFUSION. *(E.)* Collipp, P. J.; Chen, S. Y.; Maddaiah, V. T.; Thomas, J.; Huijing, F. J. (Nassau County Med. Ctr., East Meadow, N.Y.). *Pediatrics* 53(1):71-75, 1974.

An antiserum was prepared by immunizing guinea pigs with a preparation of partially purified human liver microsomal glucose-6-phosphatase. Double agar diffusion and immunoelectrophoresis revealed that this antiserum reacted with an antigen in normal human serum, and also with serum from a child with glycogen storage disease, type III, i.e., debranching enzyme deficiency. No reaction occurred with serum or liver from patients with glycogen storage disease type I. While additional experience with this method is needed, it is nevertheless a potential method for establishing the diagnosis of type I glycogen storage disease without resort to liver biopsy.

3966 NATURAL HISTORY OF AUSTRALIA ANTIGEN AND HEPATOCELLULAR CARCINOMA. *(E.)* Nishioka, K.; Mayumi, M.; Okochi, K.; Okada, K.; Hirayama, T. (Natl. Cancer Ctr. Res. Inst., Tokyo, Japan). *Proc. 3rd Int. Symp. Princess Takamatsu Cancer Res. Fund (Japan)* 1973:137-146.

Immune adherence hemagglutination (IAHA), a highly sensitive method for detection of Australia antigen, and passive hemagglutination (PHA), a sensitive method for detection of Australia antibody, are used in large-scale seroepidemiological studies. In contrast to the results by the conventional immunoelectrosyneresis method, the results obtained by IAHA showed that the positive percentage increased 1.5% in the blood donors' group, and 2.7% in the hepatitis group. A remarkable increase in the positive rate, as high as 32.2%, was observed in the hepatocellular carcinoma group. Significantly higher frequency of Australia antigen positive cases was observed in the carcinoma groups as compared with control groups in various parts of Japan, in Taiwan, the Philippines, Singapore, and Kenya. A significantly greater number of patients with hepatocellular carcinoma have Australia antigen but in levels so low as to be detectable only by sensitive methods such as IAHA. Australia antigen positive hepatocellular carcinoma show much less lymphoid cell infiltration classified as inactive cirrhosis as compared with Australia antigen negative hepatocellular carcinoma with cirrhosis. This suggests that an impaired immunologic mechanism against Australia antigen is present among Australia antigen positive hepatocellular carcinoma cases. Clustering of Australia antigen in the cases of familial chronic liver diseases suggests the early transmission of hepatitis B virus from mother to child at an immunologically immature state. Studies indicate transmission of hepatitis B virus from an Australia antigen positive mother to child at the time of delivery or at an early neonatal stage, at a stage when children are considered to be at an immunologically immature state favorable for chronic Australia antigenemia with low immune responses as have been observed in many cases of oncogenic virus infection in experimental animals. Pathological examination has revealed that some type of primary carcinoma of the liver occurs in patients with chronic liver diseases and a close relation between liver cirrhosis and hepatocellular carcinoma has been observed. In Japan the relative risk of developing hepatocellular carcinoma was 22.6 times higher in Australia antigen positive persons than in Australia antigen negative persons when measured by the IAHA method. An antigen positive rate for healthy subjects among Taiwanese, Chinese (Singapore), Malays, Indians, and others closely paralleled the frequency of hepatocellular carcinoma in each ethnic group.

3967 ARTERIOHEPATIC DYSPLASIA. FAMILIAL PULMONARY ARTERIAL STENOSIS WITH NEONATAL LIVER DISEASE.

(E.) Watson, G. H.; Miller, V. (Roy. Manchester Children's Hosp., Manchester, England). *Arch. Dis. Child.* 48(6):459-466, 1973.

A new syndrome, called arteriohepatic dysplasia, is described. It features congenital pulmonary arterial stenosis, neonatal liver disease, and various facial and skeletal anomalies. The study was based on 5 famalies with 31 children, of whom 11 had liver involvement, 14 had cardiovascular abnormalities, and 9 had both conditions. The nature of the liver lesions varied widely, showing neonatal hepatitis, extra- or intrahepatic biliary atresia, or only a mild chronic impairment of function. Liver function tests in the children gave a variable pattern, in some a moderate rise in transaminases, in some a high phosphatase, suggesting biliary obstruction. In the patients, liver function appeared abnormal in only 2 of 8 tested. Labile systolic hypertension was unduly common in apparently affected parents, but none had clinical signs of peripheral systemic arterial stenosis. The familial tendency suggested autosomal dominant inheritance, with variable penetrance. A primary defect, perhaps not uniformly distributed in all the cases, in the hepato-canalicular region might account for all hepatic manifestations. The cases may support the theory that biliary atresia and neonatal hepatitis represent different phases of the same fundamental disease process.

3968 CYANOSIS IN CHRONIC LIVER DISEASE.

(Dut.) Schalm, S. W. (no affil.). *Tijdschr. Gastroenterol.* 15(6):385-388, 1972.

A 19-yr-old man with cryptogenic cirrhosis, esophageal varices, splenomegaly, and low WBC and platelet counts was splenectomized, but part of the left lobe of the liver had to be removed because of recurrent hemobilia after splenectomy. After 4 hr the patient developed dyspnea on exertion which increased in severity following recurrent gastrointestinal bleeding. With the exception of abnormal BSP retention, liver function tests were normal, as were pulmonary function tests and chest x-rays. Although the cardiac output was increased, all results of physical examination and catheterization of the heart were normal. On the basis of arterial and alveolar O_2 pressures, radioactivity over the liver in the lung scan, and detection of a direct communication between the pulmonary artery and vein with angiography using a catheter in the wedge position, a diagnosis of pulmonary arteriovenous shunts was established. Although it has been reported that rutin normalizes reduced capillary blood flow resulting from arteriovenous shunts, no change occurred in the arterial O_2 pressure when the patient was given 2 doses of 50 mg each of rutin i.v. Similarly no improvement was noted after administration of a 20 g protein diet and 6 g neomycin for 5 days. No trial of L-dopa was attempted.

3969 THE VALUE OF REGIONAL PERFUSION OF ANTIBIOTICS IN MULTIPLE LIVER ABSCESSES: ONE CASE.

(Fr.) Jaeger, A.; Farhat, M.; Gharbi, S.; Guibert, C.; Louppe, A. (Farhat Hached Hosp., Sousse, Tunisia). *J. Med. Strasbourg* 4(7/8): 551-554, 1973.

A 35-yr-old woman who was hospitalized with a tentative diagnosis of lithiasic cholangitis presented with a fever of 40 C, dehydration, slight hepatomegaly, and jaundice which did not respond to penicillin, colimycin, and kanamycin. At laparotomy many small abscesses, measuring 1-3 mm in diameter, were found on the surface of the liver and microabscesses were present inside. Since drainage of the abscesses was impossible and no calculi were found, a Kehr drain was inserted and the hepatic artery was catheterized *via* the gastroduodenal artery which had been ligated. Antibiotics were perfused directly into the liver. The patient's condition became worse despite perfusion of 20 M of penicillin and 80 mg of gentamicin in physiological saline every 24 hr. An anaerobic *Streptococcus* was isolated from cultures of pus, bile, and blood. Since this organis was sensitive to terramycin and thiamphenicol, these antibiotics were perfused in doses of 1 g and 2 g, resp., every 22 hr. The patient's condition improved and her bile became purulent 11 days after surgery. Six days later jaundice and signs of infection had regressed and perfusion of antibiotics was discontinued. However, the patient developed an intestinal fistula and died of circulatory collapse immediately after surgery. Partial autopsy confirmed that hepatic abscesses had completely disappeared and no obstructions were present in the biliary tract.

3970 LIVER FUNCTION IN HYPERTENSIVE PATIENTS MORE THAN 45 YEARS OLD.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

3998 BREAST FEEDING AND SERUM BILIRUBIN VALUES DURING THE FIRST 4DAYS OF LIFE. *(E.)* Dahms, B. B.; Kraus, A. N.; Gartner, L. M.; Klain, D. B.; Soodalter, J.; Auld, P. A. M. (Cornell Univ. Med. Ctr., New York, N.Y.). *J. Pediatr.* 83(6): 1049-1054, 1973.

The relation between breast feeding and hyperbilirubinemia was studied in 199 breast-fed and bottle-fed infants during the first 4 days of life. Regardless of feeding regimen, breast- and bottle-fed groups had similar mean bilirubin values, and a similar low incidence of hyperbilirubinemia. Incidental findings included an 8% weight loss in infants who were breast fed without supplements, compared with a 4% weight loss in all other infants. Hyperbilirubinemia was not related to weight loss.

4 α_1-FETOPROTEIN AND LIVER-SPECIFIC ANTIGEN
IN VIRAL HEPATITIS TYPE B. *(E.)* Smith,
.; Barker, L. F. (U.S. Naval Hosp., Bethesda,
. *Arch. Intern. Med.* 133(3):437-439, 1974.

ial sera from 15 patients with viral hepatitis
B were tested for α_1-fetoprotein and liver-
ific antigen (F antigen) to determine the rela-
of these substances to the course of infection
to serum hepatitis B antigen (HBAg). α_1-Feto-
ein was present transiently, in concentra-
s between 50-150 ng/ml, in 11 patients, and F
igen was present transiently in 5 patients.
e were no differences in the occurrence of α_1-
protein or F antigen when icteric and nonicteric
ients were compared, nor when patients with
sient HBAg were compared with those who de-
ped persistent HBAg. The time of F antigen
ection coincided with probable hepatocellular
truction, whereas α_1-fetoprotein usually appeared
er when active hepatocellular regeneration might
ccurring.

ee experiences with cross circulation for the
eviation of hepatic coma in humans are reported.
of these patients survived and in none was there
major regeneration of the liver. In addition,
ross-circulation partner died from an acute
hylactic reaction attributed to antigens shared
previous cross-circulation donors. These cases
g the total number of reported cases of acute
tic necrosis treated by human cross circulation
21. Four of the previous patients have survived
out continuing evidence of chronic hepatic di-
se. Fourteen showed amelioration of the neuro-
ic symptoms and, of 11 patients autopsied, only
howed evidence of liver regeneration. Factors
ch appear to contribute to an unfavorable outcome
lude: a high incidence (9 of 21) of major gas-
intestinal hemorrhage; failure of the central
vous system to respond to treatment; a relatively
g period during which support may be required;
a high incidence of serious immunologic reac-
ns requiring support for longer than 5 days.
four human cross circulations for hepatic coma
ting 8 days or longer, there have been two deaths
donors resulting from immunologic reactions. Dis-
tinuation of clinical investigation into cross
culation with human donors is recommended until
ther research is conducted with animal models.

6 CYTOPLASMIC HEPATITIS B ANTIGEN IN "GROUND-
GLASS" HEPATOCYTES OF CARRIERS. *(E.)*
ziyannis, S.; Ferber, M. A.; Vissoulis, C.;
per, H. (Hippokration Gen. Hosp., Athens, Greece).
h. Pathol. 96(5):327-330, 1973.

er biopsy specimens were examined by immunofluor-
ence for hepatitis B antigen (HBAg) and by light microscopy. Two patterns of HBAg fluorescence were distinguished: 1) many hepatocytes with bright cytoplasmic HBAg-specific fluorescence in 19 out of 21 carriers with an essentially normal liver; and 2) few HBAg-containing hepatocytes, usually associated with HBAg in Kupffer cells in 9 patients with acute or chronic hepatitis and in 2 HBAg carriers with normal livers. Weak nuclear fluorescence was seen in addition in 3 patients with chronic hepatitis. On light microscopy 18 out of the 19 HBAg carriers with the first pattern of HBAg immunofluorescence contained hepatocytes with "ground-glass"-appearing cytoplasm. These characteristic cells appeared to be the HBAg-containing hepatocytes. Therefore, hepatocytes with ground-glass cytoplasm in an otherwise normal liver specimen should lead to the suspicion of a carrier state of HBAg.

4007 AN ELECTRON MICROSCOPIC STUDY OF THE STRUCTURAL POLYMORPHISM OF HEPATITIS B ANTIGEN. *(E.)* Hirschman, S. Z.; Schwartz, J.; Vernace, S.; Schaffner, F.; Ganz, C. (Mt. Sinai Sch. Med., City Univ. New York, N.Y.). *J. Infect. Dis.* 128(5):605-617, 1973.

Particulate hepatitis B antigen (HBAg), purified by several different methods, was suspended in buffers of various ionic strengths and pH and digested with peptidases, nucleases, and organic denaturing reagents. In water and dilute buffer 2 forms of HBAg predominated: tubes with cross-striations of 3-nm periodicity and small, solid round particles. The modal diameter of the small particles differed with the method of purification and the buffer. Ring forms of the round particles were very prominent in 0.125 M phosphate buffer and in 4 M urea. In phosphate buffer the tubes lost their cross-striations and seemed to uncoil. Large (40-80 nm) multistranded forms, with up to 4 lamellar-type strands, appeared in 0.125 M phosphate buffer and when HBAg was digested with 0.1% chymotrypsin. At acid pH tube forms disappeared and left mainly small round particles. It is proposed that the observed structural polymorphism of HBAg is dependent on protein-protein interactions. The small round particles may be disks of tightly wound helical protein that can stack to form tubes of various lengths.

4008 HEPATITIS IN SELECTIVE IgA DEFICIENCY. *(E.)* Benbassat, J.; Keren, L.; Zlotnic, A. (Hadassah Univ. Hosp. Med. Sch., Jerusalem, Israel). *Br. Med. J.* 4(5895):762-763, 1973.

Serum examinations by immunoelectrophoresis were performed over a 3-yr period in 2600 patients. Selective IgA deficiency was detected in 2 healthy subjects and in 10 symptomatic patients by immunoelectrophoresis of serum examinations. Five patients had hepatitis. In 3 of them the course of the disease suggested uncomplicated viral hepatitis. In the 4th the disturbance of the liver function disappeared only a yr after the onset of the disease; a liver biopsy specimen taken 7 months after onset was interpreted as compatible with chronic persistent viral hepatitis. The 5th patient had had acute hepatitis at the age of 8 yr. During the next 6 yr she remained jaundiced, with progressive splenomegaly and persistent disturbance in the liver function tests. The prevalence of selective IgA deficiency in this series was about 1:230. Selective IgA deficiency has been detected mainly among patients with recurrent infections, autoimmune disorders, or malabsorption, but also among asymptomatic individuals. IgA is believed to play an important part in protecting the gastrointestinal tract. Symptoms referrable to the gut, mainly malabsorption with steatorrhoea, have been observed in patients with selective IgA deficiency. It seems likely that a defect in the normal protective action of IgA in the alimentary tract, combined with a mild defect in humoral immunity, could result in a higher tendency to infections by viruses, the portal of entry of which is the gut.

4009 AUSTRALIA ANTIGEN AND THE IMMUNE RESPONSE IN HUMAN DISEASES. *(E.)* Sutnick, A. I. (Inst. Cancer Res., Philadelphia, Pa.). *J. Allergy Clin. Immunol.* 53(1):42-51, 1974.

Thirteen populations, many in the tropics, with a high frequency of persistent Australia antigen (Au) were investigated. There was a higher prevalence of persistent Au in males than in females, and an apparent relation between susceptibility to persistent Au and leukemia. Patients with Down's syndrome are a prototype for this susceptible group since they have a high frequency of persistent Au and an incidence of leukemia probably 150 times higher than that of a normal population. Data for 109 families (Italy and Melanesia) implied that the mechanism for development of persistent Au is by autosomal-recessive inheritance with a superimposed factor of maternal transmission. Comparison of mothers of leukemia patients with mothers of normal children showed that leukemia mothers had higher IgM, IgG, and antistreptolysin-O titers and history of cancer in the family. These mothers also had significantly lower monocyte counts, suggesting a host defense against transformed cells. Radioimmunoassay indicated the presence of Au-like activity in the leukemia mothers. The presence of persistent Au depends not only on susceptibility, but also on exposure to the agent. Frequency of persistent Au is higher in drug users and prisoners than in the normal population, higher in multiply transfused leukemia patients than in nontransfused leukemia patients, and higher in Down's syndrome patients in large institutions than in those living at home. Lepromatous leprosy and hepatoma patients have a higher frequency of persistent Au in countries with a high frequency of persistent Au among the normal population. Subtyping provides a method for distinguishing between the genetic hypothesis to explain family clustering of persistent Au and a hypothesis of simple infection within the family. Testing of 32 families in Bougainville revealed 11 different Au subtypes, thus ruling out the hypothesis that persistent Au results from intrafamilial infection alone.

LIVER AND BILIARY TRACT

Chronic Hepatitis

8 DANE PARTICLES IN THE SERA OF PATIENTS WITH
CHRONIC AGRESSIVE HEPATITIS. *(E.)* Yamada,
Kobayashi, T.; Tsuji, T.; Ohta, Y.; Kosaka, K.
ayama Univ. Med. Sch., Japan). *Tohoku J. Exp.*
. 111(1):93-95, 1973.

ctron microscope study showed Dane particles
sera of all 10 patients with Australia antigen-
itive chronic aggressive hepatitis. Massive Dane
ticles were demonstrated in sera of a patient at
early phase of the elevation of SGPT up to 2020
men U. The inner body of a Dane particle was
wn to have a typical icosahedral symmetry by the
ation technique.

29 HEPATITIS ASSOCIATED ANTIGEN (HAA), HL-A
ANTIGENS AND AUTO-LYMPHOCYTOTOXINS (CoCoCy)
CHRONIC AGGRESSIVE AND CHRONIC PERSISTENT HEPA-
TIS. *(E.)* Bertrams, J.; Reis, H. E.; Kuwert,
Selmair, H. (Inst. Med. Virol. Immunol., Univ.
sen, Germany). *Z. Immunitaetsforsch.*
5(4):300-307, 1974.

e incidence of hepatitis associated antigen (HAA),
stocompatibility antigens (HL-A), and cold-
ading complement-dependent lymphocytotoxins was
mpared in 77 patients with chronic aggressive
hepatitis and 51 patients with chronic persistent hepatitis. The HL-A antigen W 18 occurred with a normal frequency of 7.8% in chronic aggressive hepatitis patients but with a frequency of 25.5% in chronic persistent hepatitis patients. HAA occurred in 48% of the chronic aggressive hepatitis patients and in 72.6% of patients with chronic persistent hepatitis. The complement-fixation titer of HAA was significantly higher in the 37 HAA-positive chronic persistent hepatitis patients (mean 1:384) than in the 37 HAA-positive chronic aggressive hepatitis patients. Auto-lymphocytotoxins occurred significantly more often in patients with chronic aggressive hepatitis (48.1%) than in those with chronic persistent hepatitis (13.7%) or in 100 healthy controls (6%). The auto-antibody was demonstrated predominantly in undiluted sera and rarely exceeded a titer of 1:2 to 1:4. These results support the view that host response to HAA, which determines the clinical course of chronic hepatitis, is controlled by genetic factors. One of these factors may be linked to the histocompatibility antigen W 18.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

4035 CYTOPLASMIC CRYSTALLINE REGIONS IN HEPATOCYTES OF LIVER BIOPSY SPECIMENS. *(E.)* Burns, W. A.; Vander Weide, G.; Goldstein, L. I.; Chan, C. H. (VA Hosp., Washington, D.C.). *Arch. Pathol.* 97(1):43-45, 1974.

Cytoplasmic crystals in human hepatocytes were demonstrated in 2 patients with alcoholic liver disease and in 2 with drug hepatotoxicity attributed to isoniazid and nitrofurantoin, resp. The light microscopic and ultrastructural changes other than the crystals were variable in all cases. However, mitochondrial changes were present in all biopsy specimens and, in 1 case, the mitochondria contained a similar crystalloid type of inclusion. The crystals were found infrequently in the cytoplasm and had a sharp outline with no limiting membrane. The whole crystal measured 2.0 to 5.0 μ by 1.4 to 2.4 μ. Their periodicity gave the crystals a "herring bone" appearance in some sections. The nature of the crystals is unknown at present, but the molecular weight range is probably similar to large protein molecules, ribosomes, and viruses. Although only 13 previous cases of this entity have been reported, the finding of 4 cases in less than a year suggests the true frequency of these crystals might be proportional to the amount of material examined.

4036 MALLORY BODIES AND GIANT MITOCHONDRIA: TWO DIFFERENT STRUCTURES IN LIVER BIOPSIES FROM ALCOHOLICS. *(E.)* Bianchi, L.; Winckler, K.; Mihatsch, M.; Rohr, H. P. (Dept. Pathol., Univ. Basel, Switzerland). *Beitr. Pathol.* 150(3):298-310, 1973.

In selected liver biopsies from alcoholics, 2 types of cytoplasmic inclusions were found. Their distinct features are recognizable in light microscopy paraffin and semi-thin sections, also in ultrathin sections by electron microscopy. By alternating semi-thin and ultra-thin sections (Sandwich method) these "hyaline" inclusions have been classified as either true Mallory bodies Types I and II, or giant mitochondria with 2 forms, round and cigar-shaped. The 2 variants of Mallory bodies correspond to filamentous structures in electron microscopy and show differences only in matri density. The sharply defined round or cigar-shaped "hyaline" inclusions seen in light microscopy ultrastructurally always represent giant mitochondria which reveal no structural relation to Mallory bodies. It is suggested that the filaments of Mallory bodies are not derived from rough endoplasmic reticulum membranes. However, they may represent a protein produced by rough endoplasmic reticulum which cannot be utilized by the cell. Giant mitochondria are considered less specific for human alcoholic liver disease than are Mallory bodies.

4037 NATURAL HISTORY OF ALCOHOLIC HEPATITIS. IV. GLYCOSAMINOGLYCURONANS AND COLLAGEN IN THE HEPATIC CONNECTIVE TISSUE. *(E.)* Galambos, J. T.; Shapria, R.(Emory Univ. Sch. Med., Atlanta, Ga.). *J. Clin. Invest.* 52(11):2952-2962, 1973.

The extractable and nonextractable collagen and glycosaminoglycuranans (GAG) were estimated and characterized in 32 dried, defatted human livers obtained at autopsy from 10 nonalcoholic patients with no liver disease and 22 alcoholic patients with fatty liver (5), alcoholic hepatitis (7), and cirrhosis (10). Livers with alcoholic hepatitis or cirrhosis had significantly increased total and 1 N NaCl-extractable collagen. Only alcoholic hepatitis livers had significantly increased Tris-buffer-extractable GAG, but the amino acid composition of these GAG (proteoglycans) did not differ from that of normal livers. The major fraction of these GAG had isoelectric pH (pI) $\lesssim$ 3.1 in all livers. Livers with alcoholic hepatitis or cirrhosis had significantly increased nonextractable GAG. The major GAG fraction of all livers was chondroitin-4 or -6-SO$_4$. Alcoholic hepatitis livers had a significant increase of hyaluronic acid and an unidentified hyaluronidase-resistant GAG. Fatty livers showed no differences from normal ones. The data indicate that alcoholic hepatitis, but not fatty liver, is associated with significantly increased fibroblast activity. The changes in histologically "inactive" micronodular cirrhosis of alcoholic pa-

ts indicate continued activity of fibroblasts in
connective tissue of these cirrhotic livers.

Cirrhosis

) HEPATIC CIRRHOSIS: A CLINICO-PATHOLOGICAL
REVIEW OF 520 CASES. *(E.)* MacSween, R.
I.; Scott, A. R. (Western Infirm., Glasgow, Scot-
d). *J. Clin. Pathol.* 26(12):936-942, 1973.

linico-pathological review of 520 patients with
atic cirrhosis coming to necropsy at a Glasgow
pital between 1900 and 1969 is reported. There
been an overall increase in the incidence of
rhosis since the 1940's, and this is largely due
a rise in female incidence. A similar trend in
period 1940-1947 has been confirmed at a na-
nal level in data from the Annual Reports of the
ister General for Scotland. The mean age at
th has risen for both sexes. Etiologically, the
rhosis was alcoholic in 18.5% of the 520 patients,
ticteric in 10.4%, and cryptogenic in 61.9%; hemo-
omatosis was diagnosed in 7.5%. Primary malig-
t tumors of the liver supervened in 12.3%. Death
attributable to progressive hepatic failure in
cases, precipitate hepatic failure in 168,
nary malignant tumor in 65, and to other causes
122 instances. In 71.8% of the 238 cases for
ch postmortem liver tissue was available, the
rhosis pattern was macronodular or predominantly
ronodular/mixed. Among the 96 alcoholic cases,
histological pattern was macronodular in 65.1%.
s finding emphasizes previous observations that
h necrosis and collapse developing, micronodular
"nutritional" cirrhosis progresses to resemble
t seen in end-stage liver disease from various
ses.

1 HEMODYNAMIC VARIABLES AND PROGNOSIS FOL-
LOWING PORTACAVAL SHUNTS. *(E.)* Burchell,
R.; Moreno, A. H.; Panke, W. F.; Nealon, Jr.,
F. (St. Vincent's Hosp. Med. Ctr., New York, N.Y.).
g. Gynecol. Obstet. 138(3):359-369, 1974.

prognostic significance of large and small por-
flows was evaluated by direct measurements per-
med over a 10-yr period on 145 cirrhotic patients.
these patients 55 had an end-to-side portacaval
nt and 90 had a side-to-side anastomosis. Mean
tal flow in the 145 patients was 445 ml/min.
re were no correlations between the volume por-
flow and the incidence of encephalopathy, hos-
al mortality, or long-term survival. Pressure
ferences, estimates of total hepatic blood flow,
and splenoportographic findings did not approximate portal flow to any recognizable extent; additionally, they were of no value in predicting clinical course or survival rates after conventional portacaval decompression. Consequently, there is no justification in using these variables to classify patients into characteristic groups. Since the same rates of complications and survival occurred after diversion of either small or large portal flow, the data do not justify the use of portal flow as a criterion for selecting patients for new operations designed to preserve portal perfusion of the liver. If these operations can improve the clinical course, while still providing adequate portal decompression, they should be offered to all patients regardless of the magnitude of their flow.

4042 HEPATIC COMA IN CIRRHOSIS, PORTAL HYPERTENSION, AND FOLLOWING PORTACAVAL SHUNT: ITS ETIOLOGIES AND THE CURRENT STATUS OF ITS TREATMENT. *(E.)* Fischer, J. E. (Massachusetts Gen. Hosp., Boston). *Arch. Surg.* 108(3):325-336, 1974.

The pathogenesis of hepatic coma is discussed. The variety of conditions and situations which may result in hepatic encephalopathy has led to the concept of "increased cerebral sensitivity" in patients with chronic liver disease; the assumption is that toxins, presumably of gut origin, are responsible for the development of hepatic encephalopathy. Substances which have been implicated include various amino acids, ammonia, glutamine, short-chain fatty acids, serotonin, and false neurochemical transmitters. It is possible that all forms of hepatic coma are not caused by the same condition or substance. Severe hepatic coma may result from such factors as alcohol, the chronic absence of portal vein flow, or ornithine decarboxylase. Therapy of hepatic coma consists of removing the offending agent and, in situations where gastrointestinal tract hemorrhage is present, purging the tract of blood and controlling the hemorrhage. General supportive measures include maintenance of the fluid and electrolyte balance. Attention should also be given other possible causes of coma in patients with hepatic failure. Most established, effective therapy is directed at decreasing the protein load and "sterilizing" the intestinal contents. Forms of therapy that are not well established include various perfusion techniques, levodopa therapy, and liver transplantation. Future progress in the treatment of hepatic encephalopathy will depend primarily on the identification of the toxic factors responsible.

4043 THE ROLE OF HEMODYNAMIC MEASUREMENTS IN PORTOSYSTEMIC SHUNT SURGERY.

(E.) Reynolds, T. B. (Univ. Southern California Med. Sch., Los Angeles). *Arch. Surg.* 108(2):276-281, 1974.

Currently, preoperative hemodynamic measurements are of limited value in the selection of patients for portosystemic shunt surgery. Wedged hepatic vein pressure measurement accurately assesses portal pressure in alcoholic liver disease and can be helpful in the diagnosis and follow-up of portal hypertension but not in the selection of patients for surgery. Although theoretically useful, hepatic blood flow measurement has not been demonstrated to correlate with surgery results. New methods have been developed for the preoperative measurement of portal blood flow; these methods make use of the umbilical vein approach. Assessment of the hepatic arterial response to portal flow diversion is also feasible with the patient under local anesthesia. Hopefully, one of these measurements will prove useful in selecting those patients who can undergo portosystemic shunt without a high risk of postoperative encephalopathy or hepatic failure.

4044 THERAPEUTIC PORTACAVAL SHUNT. PRELIMINARY DATA ON CONTROLLED TRIAL AND MORBID EFFECTS OF ACUTE HYALINE NECROSIS.

(E.) Mikkelsen, W. P. (Univ. Southern California Sch. Med., Los Angeles). *Arch. Surg.* 108(3):302-305, 1974.

Of 69 alcoholic patients with cirrhosis, 35 were treated medically and the remaining 34 were treated surgically with a portacaval shunt. There have been 18 deaths in the medically treated group *versus* 9 in the surgically treated group. Recurrent encephalopathy occurred in 7 of the surgical patients and in none of the medical patients. There have been 121 separate bleeding episodes among the medically treated patients and 3 such episodes among the surgically treated patients. Of 40 additional patients with cirrhosis, 28 were treated via portacaval shunt. Among the 9 patients with or without a minimal degree of acute hyaline necrosis, operative mortality was within an acceptable range of about 4%. Progressive lethality occurred with increasing severity of the disease. Thus, it is recommended that a liver biopsy precede consideration of either an emergency or an elective shunt.

4045 CARBOHYDRATE INTOLERANCE IN IDIOPATHIC HAEMOCHROMATOSIS AND CIRRHOSIS OF THE LIVER.

(E.) Stocks, A. E.; Powell, L. W. (Dept. Med., Univ. Queensland, Brisbane, Australia). *Q. J. Med.* 42 (168):733-749, 1973.

The carbohydrate tolerance of 33 patients with hemochromatosis and 21 patients with cirrhosis from other causes was compared by studying their oral glucose tolerance and insulin sensitivity. Sixteen subjects with normal glucose tolerance and 27 with idiopathic diabetes mellitus were also studied. Sixty-three pe cent of the hemochromatosis patients and 57% of the cirrhosis patients had abnormal glucose tolerance, the derangement being more severe in the former. Th plasma insulin response to glucose (50 gm in 200 ml of water) was deficient and delayed in diabetes, excessive and delayed in cirrhosis, and relatively deficient but prompt in hemochromatosis. Insensitivity to i.v. insulin (0.1 U/kg) was more pronounced in hemochromatosis and cirrhosis than in idiopathic diabetes mellitus. There was no difference in insulin response or insulin sensitivity between untreate hemochromatosis patients and patients treated by venesection. However, one subject showed improvemen in carbohydrate tolerance with a greatly increased insulin response after iron depletion by venesection Five patients with iron overload without hepatic fibrosis had normal glucose tolerance and normal insulin response to glucose. The familial incidence of known diabetes in hemochromatosis was 24%. In contrast, 29% of the cirrhosis patients and 41% of the diabetic patients had a family history of diabetes. The vascular complications of diabetes were common in the diabetic and hemochromatosis patients, but uncommon in the cirrhosis patients. In patients with cirrhosis from any cause, there is insulin insensitivity, which is largely responsible for their carbohydrate intolerance. In hemochromatosis an additional factor is operative, and pancreatic damage from iron is more important than inheritance of the gene for diabetes.

4046 AUSTRALIA ANTIGEN AND ALPHA-FETOPROTEIN IN RELATION TO MORPHOLOGY OF CIRRHOSIS AND/OR HEPATOMA.

(E.) Sakurai, M.; Miyaji, T. (Osaka Univ Med. Sch., Japan). *Proc. 3rd Int. Symp. Princess Takamatsu Cancer Res. Fund (Gann,* 1973:127-135.

Morphological findings from autopsy cases on background liver with hepatoma suggest an impaired immun mechanism correlated with Australia antigen. The incidence of positive Australia antigen is twice as high in cirrhosis with hepatoma as in cirrhosis without hepatoma. Morphological examination of the background liver with hepatoma was carefully done under gross and light microscopes. Polymorphonuclear leuk cytic infiltration was thought most likely a secondar change due to terminal events. Activity of the cirrhosis was judged by lymphocytic infiltration in the stroma. If all types of cirrhosis are included, active cirrhosis indicated as positive lymphocytic infiltration shows that 13 of 15 cases (87%) are Austra lia antigen negative. If the cirrhosis appeared inactive, indicated as negative lymphocytic infiltration, 7 of 12 cases (58%) are Australia antigen positive. Seven of 9 cases (78%) of the Australia antigen positive cirrhosis are inactive and 13 of 18 cases (72%), of Australia antigen negative cirrhosis are active. Of the α-fetoprotein positive hepatoma cases 33% were Australia antigen positive.

4047 CELL-MEDIATED IMMUNE RESPONSE IN PRIMARY BILIARY CIRRHOSIS TO A PROTEIN FRACTION FROM HUMAN BILE.

(E.) Eddleston, A. L. W. F.; McFarlane, I. G.; Mitchell, C. G.; Reed, W. D.;

liams, R. (King's Coll. Hosp. Med. Sch., London, land). *Br. Med. J.* 4(5887):274-276, 1973.

l-mediated immune responses to a protein fraction uman bile were demonstrated, using the leucocyte ration test, in 8 out of 10 patients with primary iary cirrhosis but in only 3 out of 9 with active onic hepatitis. In the latter condition sensiti- ion to a liver-specific hepatocellular antigen found more frequently (5 out of 9 patients) than primary biliary cirrhosis (2 out of 10). These ults, as well as the granuloma formation observed tologically, suggest that the initial bile duct ion in primary biliary cirrhosis may be associated h a cell-mediated response to antigens, perhaps ived from bile duct epithelial cells, which may normal constituents of hepatic cells.

8 MAST CELLS IN HUMAN LIVER TISSUE: INCREASED MAST CELL NUMBER IN RELATION TO THE COMPO- TS OF CONNECTIVE TISSUE IN THE CIRRHOTIC PROCESS.) Murata, K.; Okudaira, M.; Akashio, K. (Univ. yo Sch. Med., Japan). *Acta Derm. Venereol. [Suppl.] ockh.)* 73:157-166, 1973.

hological changes of mast cells were studied in parison with the normal states in the connective sue of human liver. Liver specimens were obtained m 11 normal subjects and from 64 subjects who d of various liver diseases. Mast cells, which tained granules staining metachromatically as dish-purple with toluidine blue, were detected in interstitial connective tissue of human liver, the number of mast cells increased with pro- ssion of cirrhosis. In fatty liver, mast cells e observed more often in extended and widened riportal connective tissues than in the normal ver. Histochemical characteristics of mast cells e essentially similar to those found in normal ver. The increased number of mast cells was ated to proliferation of the liver connective ssue around the pseudo-lobuli, and was closely rrelated with active fibrogenesis. In advanced ty cirrhosis, the levels of hydroxyproline), was used as a parameter of collagen present, e more than double the contents in early stages increased more than 5-fold from normal liver ues. On the other hand, HP levels in liver ease in general showed no essential differences, even related to fibrotic changes, except for some HP increases in elderly patients which were due to development of fibrosis. Elevation of the acidic glycosaminoglycans was correlated with the advance of cirrhosis. Chondroitin sulfate isomers are mainly acidic glycosaminoglycans in normal liver tissue, whereas chondroitin sulfate B increases significantly with the progress of cirrhosis, at the advanced stage in particular.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

54 LEVELS OF CEFAZOLIN IN HUMAN BILE. *(E.)* Ram, M. D.; Watanatittan, S. (Huron Road sp., Cleveland, Ohio). *J. Infect. Dis.* 128:S361- 3, 1973.

biliary secretion of cefazolin was observed in 2 tients with radiological and clinically normal bil- ry tracts, 11 patients with cholelithiasis, chronic olecystitis, and radiological visualized gall- adders, 2 patients with cholelithiasis, chronic cholecystitis, and radiologically nonfunctioning gallbladders, and 1 patient with obstructive jaundice caused by pancreatic carcinoma. Cefazolin was excreted in the bile within 90 to 120 min after i.m. injection. In both the normal patients and the patients without obstructive biliary disease, the concentration of cefazolin in the bile was generally at least three times higher than the concentration in the serum. High cefazolin concentrations were also found in gallbladder tissue. Cefazolin may be useful in the treatment of biliary infections caused by susceptible bacteria.

4055 CHOLECYSTOKININ CHOLECYSTOGRAPHY IN ACALCULOUS GALLBLADDER DISEASE. *(E.)*
Nora, P. F.; McCarthy, W.; Sanez, N. (Northwestern Univ. Med. Sch., Chicago, Ill.). *Arch. Surg.* 108(4):507-511, 1974.

Symptomatic acalculous gallbladder disease presents a difficult therapeutic problem. Several patients with acalculous gallbladder disease had prolonged visualization of the gallbladder following oral cholecystography with iopanoic acid (3g) even after stimulation with a fatty meal. Cholecystectomy was performed on 14 of these patients. Over a follow-up period of 10 months to 5 yr, none had a subsequent attack of gallbladder colic. Next, cholecystokinin (75 Ivy U i.v. for 3 min) cholecystography was done on 19 other patients to detect abnormal function or the presence of disease. An abnormal response with deficient emptying was demonstrated in 10 of the 19 patients in whom cholecystectomy was done. The follow-up period has been 10 months or less, but none has experienced gallbladder colic. The operative and pathological findings for the 24 operated cases included: thickness of the gallbladder wall, kinking of the cystic duct, chronic cholecystitis, papilloma, and cholesterolosis. Cholecystokinin cholecystography added a dimension to the diagnosis of clinically important abnormal gallbladder function by providing maximum stimulus to contraction of the gallbladder that had been shwon by conventional cholecystography to empty very slowly.

4056 EFFECT OF CHLOROPHENOXYISOBUTYRATE ON LIPIDS IN SERUM AND HEPATIC BILE. *(E.)*
Saitoh, T.; Nakamura, N.; Takahashi, W.; Kobayashi, N. (Tohoku Univ. Sch. Med., Sendai, Japan). *Tohoku J. Exp. Med.* 110(4):341-345, 1973.

Changes in lipid concentration in serum and hepatic bile were investigated in patients with gallstones before and after treatment with chlorophenoxyisobutyrate (CPIB). After 14 days of 1.5 g/day CPIB treatment, there was no significant change in the cholesterol and phospholipid concentration in serum; the level of serum triglycerides was significantly reduced. Significant increase of cholesterol and phospholipid in bile was observed after 14 days of CPIB treatment. These results seem to indicate that CPIB increases the cholesterol and phospholipid levels in bile. It is suggested that CPIB, an inhibitor of cholesterol synthesis in the liver, may promote excretion of cholesterol into bile.

4057 EXCRETION OF CLINDAMYCIN IN THE BILE OF PATIENTS WITH BILIARY TRACT DISEASE. *(E.)*
Sales, J. E. L.; Sutcliffe, M.; O'Grady, F. (St. Bartholomew's Hosp., London, England). *Chemotherapy* 19(1):11-15, 1973.

Excretion of clindamycin in bile after p.o. administration was studied in 22 patients. Samples of bile were taken either directly from the gall-bladder and common duct or post-operatively from a T tube. Clind amycin was rapidly excreted in the bile, peak levels being found after 2 hr. High concentrations were found in the bile of the common duct and in those pat with radiologically functioning gallbladders. The gallbladder bile of those patients with radiological non-function was found to contain clindamycin but in a lower concentration than the functioning gallbladders. The penetration of clindamycin into the bile in radiologically non-functioning gallbladders in concentrations exceeding the minimum inhibitory concentrations for Salmonella suggests that a trial of its use in typhoid carriers would be justified.

GENERAL

ISOLATION OF CANDIDA SPECIES FROM THE GASTROINTESTINAL TRACT IN MALNOURISHED CHIL-
. *(E.)* Gracey, M.; Stone, D. E.; Suharjono;
o (Princess Margaret Children's Med. Res. Fdn.,
, Australia). *Am. J. Clin. Nutr.* 27:345-349,

ates of isolation of various species of *Candida*
gastric and small intestinal contents were
ed in 3 groups of patients: 27 relatively well-
shed Australian children of Caucasian extrac-
, and 2 groups in which malnutrition is endemic
ustralian aboriginal children and 27 Indonesian
ren). The rate of isolation of *Candida* species
ignificantly increased in the gastric and intes-
contents of the malnourished children. The
es of *Candida* found in the 3 groups differed
ly. Isolation of the known pathogen *C. albi-*
was uncommon in well-nourished children; *C.*
calis and *C. parapsilosis* were predominant in
alnourished children. The reasons for these
rences are obscure and may be related to genetic
vironmental differences or to undetermined se-
e of malnutrition. Impaired immunological sur-
ance in the malnourished children may play a
ficant role. It is noted that the increased
ence of *Candida* species in the gut of these
ren may contribute to the problem of diarrhea
lnutrition.

AETIOLOGICAL SIGNIFICANCE OF VIRUSES AND ROLE OF LYMPHOCYTES IN CERTAIN GASTROIN-
NAL DISEASES. *(E.)* Nasz, I.; Kulcsar, G.; Dan,
Sallay, K.; Vertes, L.; Geck, P.; Keskeny, S.;
ath, J. (Semmelweis Univ. Med. Sch., Budapest,
ary). *Acta Microbiol. Acad. Sci. Hung.* 20(3):
203, 1973.

oximately 10,000 preparations from nearly 500
ents and healthy controls were examined. Cells of scrapings of oral ulcers and lymphocytes were studied with immunofluorescence and the lymphocyte transformation test, as well as with the rapid swelling reaction of lymphocytes under viral effect. Adenovirus and herpesvirus antigens were significantly more often detected in the lymphocytes of aphthous patients than in controls. Frequently the simultaneous presence of the 2 types of virus was observed in both cell types of the same patient. A positive lymphocyte transformation reaction with type 1 adenovirus was noted in about 2/3 of the patients. Similar results with herpesvirus were noted in 1/2 the patients. A similar incidence was found with the rapid lymphocyte swelling reaction. In the 14 patients with ulcerative colitis, the lymphocyte transformation test was 36.4% positive with the latent adenovirus types 1, 2, 5, and 6 while with herpesvirus this rate was 17% in 10 patients with hepatic cirrhosis and 20% in 10 patients with diabetes mellitus, which refers to a sensitivity of the cells to those viruses. In contrast, only 6-8% positive results were seen in patients with other diseases and healthy persons. Such results suggest that viruses or virus antigens and lymphoid cells may be important in the development of chronic and recurrent digestive tract diseases of unknown etiology. The simultaneous presence of adeno and herpesvirus antigens may be connected with these diseases and their recurrence. Virus-induced disturbances of the immune reaction may be important. In the cases in this series cellular immunity appeared to be disturbed. As the epithelial cells of the mucosa and lymphoid cells are connected, viruses causing periodic diseases are released from the mononuclears into epithelial cells and induce recurrences or may be significant in disturbing cellular immunity. When the lymphoid cells carrying the virus or viral gene cease to control their oncogenic effect, the disease which, up to then, had been recurrent or chronic in its features, turns into a malignant disease.

4075 ANTITOXIN RESPONSES TO INFECTIONS WITH ENTEROTOXIGENIC ESCHERICHIA COLI. *(E.)*

Sack, R. B.; Jacobs, B.; Mitra, R. (Baltimore City Hosp., Md.). *J. Infect. Dis.* 129(3):330-335, 1974.

Titers of antitoxin to the enterotoxins of *Escherichia coli* and *Vibrio cholerae* were determined in acute and convalescent sera from 23 patients with acute cholera-like diarrhea in Calcutta, India. The adult rabbit ileal loop model was used for titration of antitoxin. Of 8 patients harboring enterotoxigenic *E. coli*, 6 developed 4-fold or greater rises in titer of antibody to *E. coli* enterotoxin. Similar findings were noted in 4 of 10 patients who were bacteriologically negative. Of 6 patients with cholera, 5 also showed significant rises in antitoxin titer against the *E. coli* enterotoxin, suggesting extensive immunologic cross-reactions between these 2 enterotoxins. In 2 of the cholera patients the existence of dual infection suggested the possibility that an interaction between *V. cholerae* and *E. coli* was occurring in the jejunum with passage of an enterotoxin-mediating plasmid. These studies suggest that antibodies to enterotoxin are regularly formed after infection with enterotoxigenic *E. coli*, and that antitoxin assays might be useful in making retrospective diagnoses of disease caused by these organisms in areas in which cholera is not endemic.

4076 USE OF CHEMICALLY DEFINED DIETS IN THE MANAGEMENT OF PATIENTS WITH HIGH OUTPUT GASTROINTESTINAL CUTANEOUS FISTULAS. *(E.)*

Rocchio, M. A.; Mo Cha, C.-J.; Haas, K. F.; Randall, H. T. (Rhode Island Hosp., Providence). *Am. J. Surg.* 127(2):148-156, 1974.

In 37 patients with gastrointestinal cutaneous fistulas, a major effort was made to maintain nutrition throughout the emergency period. In 26 patients i.v. nutrition was followed by the use of a chemically defined elemental diet. In the remaining 11 cases the elemental diet was the initial method used to provide nutrition. Inflammatory bowel disease was associated with the fistulas in 10 cases, abdominal trauma in 3, and peptic ulcer in 3. Malignant lesions were directly associated with the fistulas in 11 cases. It is essential that the diet introduced into the stomach or a segment of the small bowel be gradual and continuous. Initial concentration must not exceed 10-15% weight/volume of a high nitrogen diet in the adult and should be less in children. Adult patients should receive 40-60 ml/hr at first, with the concentration and volume gradually increasing over 3 to 4 days, with monitoring of the blood and urine glucose and electrolytes, until 45 to 60 calories/kg/day are tolerated. Vitamin supplementation, including vitamin K and probably folic acid, is needed. In this series 24 patients had spontaneous closure, which included 7 of 12 proximal fistulas, 8 of 16 small bowel fistulas, and all 9 colonic fistulas. Surgical closure was needed in 6 patients. There were 6 deaths, 4 from cancer, 1 from infarction of additional small bowel and 1 due to massive hemorrhage of the gastrointestinal tract.

4077 RADIOLOGICAL CHANGES IN THE DISTAL PART OF THE ILEUM IN ASSOCIATION WITH YERSINIA ENTEROCOLITICA INFECTIONS. *(E.)*

Van Wiechen, P. J. (Univ. Hosp., Leiden, Netherlands). *Radiol. Clin. Biol.* 43(3):242-253, 1974.

Three women (aged 23-34 yr) presenting symptoms suggestive of Crohn's disease required radiological examination of the small intestine using the enteroclysis procedure. In 2 of the patients, the history of cramp-like abdominal pains was short, 4 weeks, and in the other the pain commenced after an appendectomy 2 years earlier. In each case radiological examination showed changes in the mucosa of the ileum, limited to the terminal 20 cm. Filling-defects were noted, a few with a diameter of 5-7 mm, which were probably based on hyperplasia of lymphoid tissue. The mucosal folds, showing a very tortuous course, were increased in number and noticeably broadened. The distance between the distal ileum and the adjacent cecal loops was increased. Both the broad folds and the increased distance between intestinal loops were due to inflammatory edema in the circular folds and the intestinal wall, resp. Only sometimes did the filling-defects resemble the cobblestone appearance common in Crohn's disease. Furthermore, in Crohn's disease, there is no increas in the number of mucosal folds. The radiological findings in these patients were also distinctly different from those of nodular lymphoid hyperplasia in which the filling-defects are regularly arranged and rarely exceed a diameter of 1-3 mm. It is stressed that a diagnosis of *Yersinia enterocolitica* infection be considered when cases present with a brief and not entirely typical history for Crohn's disease diagnosis. Enterocolysis of the small intestine should be considered for these cases since conventional radiography with an oral contrast medium does not ensure optimal filling of the distal ileum. A literature review demonstrated that a *Yersinia* infection can also be involved when the symptoms suggest acute appendicitis.

4078 CARCINOID MYOPATHY AND TREATMENT WITH CYPROHEPTADINE (PERIACTIN). *(E.)*

Berry, E. M.; Maunder, C.; Wilson, M. (Hammersmith Hosp., London, England). *Gut* 15(1):34-38, 1974.

Laparotomy in a 47-yr-old woman with flushing attack and diarrhea revealed white deposits throughout the liver and gallbladder. Histology was of an argentaffin carcinoma and the primary was from the gallbladder. Over the next 2 yr the patient developed pulmonary stenosis, the diarrhea and flushing attacks became more severe, and proximal limb and girdle weakness occurred. Biopsy of the right infraspinatus muscle showed advanced atrophy of type II muscle fibers but no inflammation. Perinuclear acid phosphatase was increased. Electron microscopy revealed persistence of the Z-line with severe muscle fiber disruption similar to that observed in animals injected with 5-hydroxytryptamine (5-HT). Blood 5-HT in the patient was 2.0 μg/ml. *p*-Chlorophenylalanine (up to 4 g/day) was ineffectiv in controlling the diarrhea. However, adding cyproheptadine (16-32 mg/day) controlled the diarrhea and

uced symptomatic improvement in muscle power.
ovement in control of diarrhea has been maintained
over 10 months on cyproheptadine alone. The
athy was apparently a nonmetastatic complication
he carcinoid tumor or was caused directly by
ulating 5-HT.

NEONATAL NECROTIZING ENTEROCOLITIS:
CLINICAL AND RADIOLOGICAL FEATURES. *(E.)*
, S. A.; Friedland, G. W. (Stanford Univ. Sch.
, Calif.). *West. J. Med.* 120(2):110-115, 1974.

trospective study was made of the clinical and
ological findings, therapy and prognosis in 10
en cases of neonatal necrotizing enterocolitis
nosed over a 3-year period. Only 3 of the
ers had no prenatal complications, and only 4
nts weighed more than 1600 g. The mean gesta-
al age was 32 weeks and the range was 28 to 38
s. All infants presented with respiratory prob-
. Hyperbilirubinemia occurred in 7 infants.
infants had rapid respirations (greater than 60
0 breaths/min), periodic breathing, lethargy and
tability before the onset of abdominal symptoms.
e nonspecific symptoms also occurred in numerous
nts who had respiratory disease and who did not
equently have necrotizing enterocolitis. Symp-
suggesting abdominal disease appeared in 6 in-
s between the 3rd and 7th day of life. Abdominal
ension was observed in all infants as one of the
iest features. The radiographic features included
eased intraluminal gas and fluid; waxing and
ng bouts of bowel distension; a "bubbly" pattern
times localized to the right lower quadrant but
uently more extensive and reflecting the extent
he disease; hepatic portal venous gas; and seg-
al dilatation, narrowed segments, thickened folds,
an irregular mucosal pattern of the small bowel.
patients were treated surgically. The other,
had congenital heart disease, was treated medi-
y with bowel decompression, broad spectrum anti-
ic therapy, and respiratory assistance. Seven
nts died. In 9 of the 10 cases, the radiologist
t made the correct diagnosis. It is concluded
early diagnosis is critical to the institution
roper therapy in premature infants with necro-
ng enterocolitis. Plain abdominal radiographs
be taken of all premature infants with abdominal
ension, vomiting, apneic spells, jaundice, or
ac-positive stools. Barium contrast studies of
small bowel and colon are of no value in making
diagnosis, and can be misleading.

LOW MOLECULAR WEIGHT DEXTRAN IN THE TREAT-
MENT OF NECROTIZING ENTEROCOLITIS AND MIDGUT
ULUS IN INFANTS. *(E.)* Krasna, I. H.; Fox, H.
Schneider, K. M.; Becker, J. M. (Mt. Sinai Sch.
, City Univ. New York, N.Y.). *J. Pediatr. Surg.*
:615-622, 1973.

use of its abilities to reduce thrombus formation,
molecular-weight dextran (10 ml/kg every 6 hr for
r, i.v.) was administered to 8 newborns with ne-
izing enterocolitis and 2 infants with midgut
ulus. The enterocolitis group which received
ran was compared with an otherwise similarly
treated group which did not receive dextran; half of the dextran-treated group did not require operation while all of the patients not receiving dextran did. Although repeated perforation and late intestinal strictures occurred commonly in the group which did not receive dextran, no dextran-treated infant demonstrated either of these complications. The patients with midgut volvulus receiving dextran demonstrated remarkable recovery of bowel at reexploration, despite the widespread ischemic appearance of bowel at initial operation. No complications from the use of dextran were encountered.

4081 STIMULATION OF INTESTINAL ADENYL CYCLASE BY ENTEROTOXIN: COMPARISON OF STRAINS FROM AN INFANT AND AN ADULT WITH DIARRHEA. *(E.)* Kantor, H. S.; Tao, P.; Gorbach, S. L. (Cook County Hosp., Chicago, Ill.). *J. Infect. Dis.* 129(1): 1-9, 1974.

The effects of *Escherichia coli* enterotoxin on the activity of adenyl cyclase in intestinal mucosa were determined in the small intestine of the rabbit. *In vivo* incubation of enterotoxin in isolated intestinal loops for 2-4 hr increased the activity of adenyl cyclase in mucosal epithelial cells. The degree of stimulation of the enzyme was proportional to the concentration of enterotoxin. The levels of activity were additive when enterotoxin-treated, homogenized mucosal cells were exposed to prostaglandin E_1. The activity of adenyl cyclase in both enterotoxin-treated and control preparations was stimulated markedly by NaF. Phosphodiesterase activity was not altered in enterotoxin-treated loops. Enterotoxin was partially inactivated when held at 60 C for 15 min; it was completely inactivated at 100 C. Differences in the degree of stimulation of adenyl cyclase were noted among strains of *E. coli*. Enterotoxin from a strain isolated in an adult in Calcutta with cholera-like diarrhea was a more potent stimulator of adenyl cyclase than enterotoxin from a strain of *E. coli* associated with a mild case of diarrhea in an infant in Chicago. Such differences may have important implications for an understanding of the epidemiology of acute diarrhea.

4082 GASTROINTESTINAL COMPLICATIONS OF PHEOCHROMOCYTOMA. *(E.)* Hunter, T. B.; Martel, W. (Univ. Michigan Med. Ctr., Ann Arbor). *J. Can. Assoc. Radiol.* 24(4):374-376, 1973.

The available roentgenograms and medical records of 24 cases of pheochromocytoma were reviewed. The patients ranged in age from 9 to 63 yr; 7 were younger than 20, 10 were between 20 and 40, and 6 were over 40. Two patients had a family history of pheochromocytoma and 2 additional patients were brothers. Nausea and vomiting were prominent symptoms in 7 and 8 patients, resp., and were usually chronic or paroxysmal and associated with other symptoms. Five patients had chronic constipation; 1 patient, a 9-year-old boy, had multiple episodes of fecal impaction, 2 patients had chronic intermittent diarrhea. There were 3 patients in whom plain films of the abdomen demonstrated gaseous dilatation of both the small and large bowel with retained fluid. In 4 patients the adrenal tumor was evident on plain roentgenograms. Necropsy, performed in 3 of the 24 cases, showed marked generalized hypertrophy of the tunica muscularis of the intestinal arteries in 1 patient, focal areas of hemorrhagic necrosis throughout the large and small bowel in the 2nd, and no significant intestinal abnormalities in the 3rd. Of the 24 case histories, 10 had well-documented hypertension for longer than 3 yr, and as long as 15 yr before the tumor was discovered. It is concluded that pheochromocytoma should be considered in the differential diagnosis of patients with hypertension who develop abdominal pain, prolonged ileus, or intestinal bleeding.

4083 NECROTIZING ENTEROCOLITIS AND EXCHANGE TRANSFUSION.

(E.) Shapiro, M.; Stein, H. (South African Blood Transfusion Service, Johannesburg). *S. Afr. Med. J.* 47(28):1236-1238, 1973.

The primary role of intestinal infection on necrotizing enterocolitis is discussed. At one Johannesburg hospital, 63 babies in a prematurity unit had diarrhea. *Salmonella* was cultured from the stools of 22 of them. Eleven developed necrotizing enterocolitis and all of these died; 2 had received exchange transfusions for hyperbilirubinemia. At another hospital, there were 19 cases of necrotizing enterocolitis in infants; 4 died. No specific pathogen was isolated. Thirteen of these babies had received exchange transfusions for hyperbilirubinemia. In the 6 months embracing both outbreaks, 269 exchange transfusions were performed by the same transfusion team in other units of the 1st hospital, and 587 in other maternity hospitals, without a single case of necrotizing enterocolitis among the 596 recipients. Although these outbreaks of necrotizing enterocolitis were unquestionably due to intestinal infection *ab initio*, the possibility remains that the exchange transfusions aggravated the necrotizing lesion in some babies. It is therefore recommended that exchange transfusion be administered with caution, and preferably withheld, if the infant has diarrhea or blood in the stools, or if intestinal infection is known to be prevalent in the unit or hospital.

4084 CONTROLLED TRIAL OF ORALLY ADMINISTERED LACTOBACCILLI IN ACUTE INFANTILE DIARRHEA.

(E.) Pearce, J. L.; Hamilton, J. R. (Dept. Pediatr., Univ. Toronto, Canada). *J. Pediatr.* 84(2):261-262, 1974.

Ninety-four children under 3 yr of age who required hospital admission because of acute-onset diarrhea were administered placebos or oral preparations of lactobacilli over a period of 10 months. No significant difference was found between the placebo and treatment groups in the number and size of stools passed for 4 days after onset of treatment. The mean duration of diarrhea in the two groups also did not differ significantly. Furthermore, the lactobacilli had no apparent beneficial effect when either short-term or long-term cases were considered separately. Thus, the data do not support the hypothesis that lactobacillus might shorten the course of acute-onset diarrhea and reduce the incidence of relapse.

4085 HAEMANGIOMAS OF THE GASTRO-INTESTINAL TRACT.

(E.) Taylor, T. V.; Torrance, H. B. (Manchester Roy. Infirm., England). *Br. J. Surg.* 61(3):236-238, 1974.

Four cases of hemangiomatous malformations of the gastrointestinal tract are described. The first case involved an 11-yr-old girl; the lesion involved the entire stomach and a total gastrectomy was performed. In the second patient, a 25-yr-old man, diffuse hemangiomas and lymphangiomas were found throug out the entire small intestine. The third patient, a 34-yr-old man, presented with a history of anemia and a primary symptom of dyspnea. Although there was no history of alimentary symptoms, laparotomy revealed numerous large hemangiomatous malformations throughout the entire intestinal tract; laparotomy also confirmed complete absence of a spleen. Laparotomy of a 38-yr-old man revealed a diffuse cavernous hemangioma which involved the whole rectum, the lower half of the sigmoid colon, and the bladder. The spleen was probably also hemangiomatous and there were numerous ascites in the abdominal cavity. Treatment involved ligation and division of both of the feeding vessels. Postoperatively, the patient developed gross ascites, but when this settled he remained asymptomatic. In general, hemangioma should be suspected when a patient presents with recurrent attacks of anemia or melena for which no other cause can be found after contrast radiography. Where possible, resection of the involved length of gut is curative. Other methods which have been employed in isolated cases are cauterization, partia extirpation, irradiation by deep X-ray therapy or implanted radon seeds, and the injection of sclerosing substances.

4086 ENDOSCOPY IN THE PEUTZ-JEGHERS SYNDROME.

(E.) Kurtz, R. C.; Winawer, S. J.; Sherlock, P. (Mem. Sloan-Kettering Cancer Ctr., New York, N.Y.). *Am. J. Gastroenterol.* 61(2):125-128, 1974.

The natural history of the Peutz-Jeghers syndrome is discussed with reference to the case of a 26-yr-old man. The patient was first hospitalized for severe, crampy abdominal pains and iron deficiency anemia. Laparotomy at that time and during subsequent hospitalization revealed several small bowel polyps. Later, upper gastrointestinal series, small bowel series, and barium enema demonstrated numerous gastric, duodenal, small intestinal, and large bowel polyps. Two large pedunculated polyps were also found at the cardioesophageal junction. The gastric and duodenal polyps were visualized with the fiberoptic gastroduodenoscope. The visual findings at endoscopy suggested bleeding from one large duodenal polyp, which later proved to be a benign hamartoma. Although Peutz-Jeghers polyps such as this one are generally benign hamartomas, there is evidence of a higher risk of malignancy in the gastroduodenal area of affected patients. As illustrated in this case, endoscopy is a valuable asset to the

troenterologist in the management of this syn-
me in that it aids in the localization of bleed-
and in the evaluation of the presence or absence
malignancy.

4105 THE LIVER IN AMOEBIC DISEASE. A REPORT ON CLINICAL AND SCINTIGRAPHIC OBSERVATIONS IN 247 PATIENTS. *(E.)* Bieler, E. U.; Meyer, B. J.; Jansen, C. R.; Du Toit, D. (Life Sci. Div., Atomic Energy Board, Pretoria, South Africa). *S. Afr. Med. J.* 48(8):308-320, 1974.

A group of 247 patients (202 males and 45 females, aged 2 1/2 to 80 yr) with amebic liver abscesses was examined by scintigraphy. Pain in the right upper abdomen or right shoulder for 3-9 weeks was present in all patients. Severe weight loss occurred in 21%, diarrhea in 28%. Hepatomegaly or a tumor was clinically evident in 87%. Vegetative amebae were found in 17%. Clinical diagnosis was liver abscess in 96%. Gastrointestinal complications included amebic peritonitis (1), amebic pericarditis (2), a fistula through the abdominal wall after drainage (2), and obstructive jaundice (1). The combination of right lateral and anterior views was sufficient to allow diagnosis in 99% of the cases. On dividing the liver into 7 regions, abscesses were restricted to one region in 126 patients while 19 had abscesses large enough to replace the whole right lobe. The most commonly affected region was the posterior upper part of the right lobe, 34%. Hospitalization was significantly longer in patients with lesions in the superior part of the right lobe than in those with lesions in the inferior part or the central parts of the liver. A relation was established between the presence of hyperbilirubinemia and the localization of the abscess. Of 13 patients with serum bilirubin above 1.3 mg/100 ml, 8 had abscesses arising in the porta hepatis, 3 had multiple lesions, of which 2 had visible portal manifestations. The remaining 2 patients had large abscesses involving the whole right lobe of the liver. In 41.5% of the cases with portal abscesses, hyperbilirubinemia was present. Thus the retention of bilirubin in hepatic amebic disease probably arises more often from mechanical factors than from insufficiency of the liver parenchyma. No significant correlation could be drawn between length of history and size of abscess. The size of the abscess apparently has no bearing on the outcome of the disease, for the abscess rarely interferes seriously with the function of the liver parenchyma. Neither the initial size of the lesion nor the type of treatment determined whether the liver would heal without severe deformation. The rate of healing of the abscess was closely related to its size in that healing is fastest at the beginning of therapy. Although the scintigraphic appearance of the liver parenchyma adjacent to the abscess was normal in most cases, a marked uneven uptake occurred in 7 patients due to reduced hepatic blood flow, disturbed function of the hepatic parenchyma, or fibrosis of the liver. An enlarged liver, clinically diagnosed in 87% of the cases, was demonstrated scintigraphically in only 69%. It is suggested that liver function tests may help differentiate amebic abscess from common conditions showing similar symptomatology.

4106 AIR AS A NEGATIVE CONTRAST MEDIUM IN THE STUDY OF AMEBIC LIVER ABSCESS. *(E.)* Ramachander Rao, S.; Murthy, K. J. R.; Chandramouli, C. (Osmania Med. Coll., Hyderabad, India). *Am. J. Gastroenterol.* 60(5):504-509, 1973.

The usefulness of atmospheric air in the delineation and follow-up of amebic abscess of the liver was studied in 20 patients. Each patient received tetracycline, chloroquine phosphate, and hydroxyquinoline. On the second day of treatment aspiration was made with a thick bore aspiration needle and 50-100 cc atmospheric air was then injected till a slight positive pressure was felt. Subsequent aspirations were made every 5th day for 5 times and then every 10th day until no pus could be further aspirated. X-rays were taken until no air was detected in the abscess cavity and progress was assessed by reduction in cavity size by screening. Air when instilled into the cavity, delineates it uniformly unlike radiopaque dyes which settle at the bottom. Multiple cavities may be visualized by this means as the air gains access to them. Studies usin air do not have the drawbacks of false positives or false negatives. It is further noted that, since the air does not remain for a long time, there is no chance of granuloma formation. None of these 20 cases had infection or air embolism. Lesions as small as 5 mm diameter have been visualized in the follow-up studies.

4107 AMOEBIC PERFORATION OF THE INTESTINE IN CHILDREN. *(E.)* Cade, D.; Webster, G. D. (Westminster Hosp., London, England). *Br. J. Surg.* 61(2):159-161, 1974.

Perforation of the intestine due to *Entamoeba histolytica* occurred in 3 patients (2 boys and 1 girl, aged 9 months to 3 yr). Presenting symptoms varied widely among the patients. The history of their illnesses ranged from 4 days to 3 weeks with all having or developing bloody diarrhea with mucus and vomiting. In all cases distension of the abdomen was present, but rigidity occurred in only 1. Bowel sounds were present until a late stage. Temperature rose in 2 cases. In 2 cases coughs were present. The misdiagnoses in these cases included *Salmonella* infection, appendicitis, intussusception, typhoid, and gastroenteritis, all of which delayed proper treatment. A fuller understanding of the fulminating nature of amebic infection in young infants and children is necessary if early diagnosis is to be made and effective treatment started. In 1 of these cases examination showed marked chest signs and it i stressed that such a finding must confirm amebiasis rather than *Salmonella* infection as a diagnosis. X-ray of 1 case revealed air under the diaphragm and in another case the colon was dilated with fluid levels at both bases of the loop. Failure to find the *E. histolytica trophozoites* in a single specimen does not exclude the disease, for they are passed only at intervals. For amebiasis of moderate severity, surgery is recommended. Conservative trea ment gives the best results in peritonitis complicating the acute fulminating type of amebic dysentery. Many complications can follow surgical procedures used in such cases. In this series perfora-

s in the transverse colon followed 2 days after
ndectomy in one case.

SIGMOIDOSCOPIC AND COLONIC MUCOSAL BIOPSY
FINDINGS IN AMEBIC COLITIS. *(E.)* Pitt-
F. E.; Hennigar, G. R. (Med. Univ. South Caro-
, Charleston). *Arch. Pathol.* 97(3):1551-1558,
.

oid colonic mucosal biopsy specimens from 9 pa-
ts with well-documented acute amebic colitis
studied. A diffuse nonspecific inflammatory
onse was characteristic of all biopsy specimens
her or not focal ulceration and trophozoites of
moeba histolytica were shown to be present.
ae were found in only 50% of pretreatment biopsy
imens in spite of extensive serial sectioning.
appearance of the mucosa at sigmoidoscopy in
group of patients was compatible with sigmoido-
ic findings in nonspecific (ulcerative) or granu-
tous colitis. It is noted that, in the absence
he amebae, the histologic characteristics of
ic colitis may be indistinguishable from other
s of colitis. Thus it is necessary to consider
ic colitis in a differential diagnosis whenever
nic mucosal biopsy specimens containing nonspeci-
inflammation are seen.

EPIDEMIOLOGICAL EVALUATION OF THE EFFI-
CIENCY OF ORAL VACCINATION AGAINST ENTERO-
OGENIC Escherichia coli. *(E.)* Kubinyi, L.;
, I.; Lendvai, K. G. (Natl. Inst. Pub. Health,
pest, Hungary). *Acta Microbiol. Acad. Sci.*
. 19(3):175-186, 1972.

rimental vaccination of hospitalized infants was
ormed with the Rauss-type trivalent oral vaccine
nst enteropathogenic *Escherichia coli* infection.
he periods 1969-70 and 1970-71, each infant
ived for basic immunization 9 and 18 tablets,
. The maintenance dose was 1 tablet weekly
ughout the period of hospitalization. The vac-
contained 0.5 mg each of freeze-dried Boivin-
extracts of *E. coli* O111:B4, *E. coli* O55:B5
E. coli O86:B7 per tablet. It dissolved readily
ea and had no noticeable side effect. A total
27 vaccines and 1040 unvaccinated controls were
rved during the experimental period. Infantile
ritis associated with *E. coli* occurred in 28
inated infants (incidence, 4.5%) and in 79 control in-
duals (incidence, 7.6%). The protective effect of
vaccine increased parallel with the age of the
inated infants, the rate of protection being 30% among
born mature and premature babies, 55% among
month-old and 74% among 3-month-old infants.
mean protective effect was 40.8%. Vaccination
no influence on the clinical course of the di-
e, nor on the incidence of symptomless excretion.
g the unvaccinated controls, the incidence of in-
ion increased parallel with the duration of
italization. The protective effect of vaccination
however, demonstrable only during the first 2
hs (65%) of hospitalization. It is suggested
the basic immunization be repeated or performed
vo with a high enough dose to render repetition
cessary if the infant is to remain hospitalized
more than 3 months. In most cases the etiological agent was *E. coli* O111:B4. The symptomless excretors excreted several other *E. coli* sero-groups as well. On the basis of the epidemiological evaluation, the vaccine appears to be a useful preventive measure against nosocomial epidemics. Since, however, delayed cases also occur, the present dosage schedule needs revision.

4110 GIARDIASIS IN CHILDREN: A STUDY OF PANCREATIC FUNCTIONS. *(E.)* Gupta, R. K.; Mehta, S. (Postgrad. Inst. Med. Ed. Res., Chandigarh, India). *Indian J. Med. Res.* 61(5):743-748, 1973.

Of 1,551 children screened, 11.1% had cysts of *Giardia intestinalis* in the stools. Diarrhea, abdominal discomfort and failure to thrive were the significant symptoms. Pancreatic function, stool fat and nitrogen excretion were studied in 25 of the children with symptomatic giardiasis and in 16 normal controls. Steatorrhea was present in 10 of the 25 giardia cases, and fecal fat excretion decreased significantly in all giardia cases following eradication of the parasite. Pancreatic lipase and trypsin activities were lower in the giardia group compared to the controls. Pancreozymin stimulation, used in 10 giardia subjects and in 6 normal controls, increased the activity of both enzymes, but the level of activity in the giardia subjects continued lower than in the controls. Stool fat excretion revealed a significant correlation with stimulating lipase activity. Such a relation was not observed between stool nitrogen and trypsin. From these results it is suggested that the parasite interferes with the action of pancreatic lipase, resulting in increased stool fat excretion. It is also suggested that an interference in the action of bile salts may occur.

4111 SCHISTOSOMAL COLONIC POLYPOSIS: ENDOSCOPIC AND HISTOLOGIC CHARACTERISTICS. *(E.)* Nebel, O. T.; El-Masry, N. A.; Castell, D. O.; Farid, Z.; Fornes, M. F.; Sparks, H. A. (Naval Hosp., San Diego, Calif.). *Gastrointest. Endosc.* 20(3):99-101, 1974.

Ten Egyptian farmers (mean age, 34 yr; range, 16 to 40 yr) with active schistosomal colonic polyposis were evaluated. The Bells egg count technique was used to estimate the intensity of *Schistosoma mansoni* infection and the MIFC technique to detect the eggs in the stools. Barium enema was employed to screen patients for presence and extent of polyps. Sigmoidoscopy and colonoscopy also were performed. Endoscopic biopsies and crush preparation were obtained for histological study. Diarrhea, hematochezia, and a long history of schistosomiasis were present in all patients. Six patients had hepatomegaly, and 5 patients had splenomegaly. Laboratory studies revealed the presence of anemia, hypoalbuminemia, and elevated alkaline phosphatase activity. Viable schistosome eggs were seen in the stools of all patients. Barium enema revealed multiple colonic polyposis in all patients. Polyps were noted from the rectum to transverse colon with the greatest concentration of polyps being found in the sigmoid colon. The polyps ranged from small mucosal excrescences to large fungating lesions. Polyps greater than 1 cm were generally covered by a white exudate, and both polyp and colonic mucosa were friable. Three patients had polyps associated with necrotic lesions. The endoscopic appearance of the schistosomal polyps and the immediate examination of the endoscopic biopsy specimen allow rapid differentiation of schistosomal colonic polyposis from other forms of colonic polyposis. The importance of this differentiation to both therapy and prognosis suggest that endoscopic observation and biopsy should be performed in all patients with suspected colonic schistosomiasis.

4112 BILHARZIAL PIPE-STEM PORTAL FIBROSIS IN ZAMBIA. *(E.)* Bhagwandeen, S. B. (Sch. Med., Univ. Zambia, Lusaka). *J. Pathol.* 111(1): 23-30, 1973.

Ten case histories of pipe-stem portal fibrosis from Zambia are presented to illustrate the clinical and necropsy findings. Hematemesis was evident in 4 cases, vomiting in 2, and cerebral malaria in 2. Cardiac failure, severe anemia, and severe ascites were each evident in 1 case. Seven of the 10 cases showed classical macroscopic features of Symmers' pipe-stem portal fibrosis. The gross liver showed pseudolobulation on the capsular surface. The capsule in all cases was smooth. Macroscopically the cut surface showed the typical dense white bands of scar tissue surrounding the portal veins. Histological examination of areas around the portal tracts showed dense fibrous scar tissue. Within these areas were a variable number of recognizable bilharzial ova and, more frequently, fragments of their chitinous covering. Angiomatoid lesions were noted in all sections with established pipe-stem fibrosis examined. Acute and healing granulomatous lesions surrounding bilharzial ova were occasionally noted within the scar tissue around the portal tracts, as well as in the finer portal radicles of the apparently healthy zones. There appear to be three stages of hepatic bilharziasis: miliary hepatic bilharziasis with acute pseudotubercles in portal tracts; intermediate proliferative stage corresponding to fibroblastic proliferation and repair around the granulomatous lesions; and late fibrotic stage characterized by fibrosis of the finer and intermediate sized portal radicles with distortion of the portal tracts.

GENERAL

Regional Enteritis

THE TREATMENT OF ILEOCOLITIS WITH ACTH
AND PREDNISONE: IMMEDIATE AND PROLONGED
CT. *(E.)* Barham, J. E.; Ruffin, J. M. (Cross-
Clin., Durham, N.C.). *South. Med. J.* 67(4):
-422, 1974.

hundred consecutive patients with ileocolitis
treated with ACTH i.v. followed by oral predni-
. Each patient received 40 U/liter ACTH as a
tinuous i.v. drip for 20 hr/day for 5-7 days,
nding on response. After the initial treatment,
l was tapered by reducing the time rather than the
for 3 days. Prednisone dosage was 10 mg three
s daily for 1 week, 10 mg twice daily for 1
, 5 mg twice daily for 1 week, and 5 mg daily
1 week. Following the initial course of treat-
, 95 patients were either symptom-free or mark-
improved. Of 90 who had subsequent courses of
apy, 80 were immediately either symptom-free or
edly improved, indicating that tolerance was
developed. In 89 patients observed for 6 months
onger, 23 were either symptom-free or had no
rrences requiring hospitalization; 66 had re-
ences requiring hospitalization for medical man-
ent or operation. Mean duration of remission
25 months (range, up to 11.5 yr). There were
ignificant differences in long-term results be-
n steroid therapy and operation. Complications
side effects were minimal or absent. Although
her the natural history of the disease nor the
l for operation is altered, the excellent immediate
ct with long periods of remission between recur-
es suggests that ACTH given i.v. followed by
oids given orally is the medical treatment of
ce for ileocolitis.

5 EPIDEMIOLOGY OF REGIONAL ENTEROCOLITIS

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX		
SUBJECT INDEX		

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

yr	year(s)

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4133 A HISTOLOGICAL AND FUNCTIONAL STUDY OF THE GASTRIC MUCOSAL INNERVATION IN THE DOG. PART I: THE QUANTIFICATION OF THE FIBRE CONTENT OF THE NORMAL SUPRADIAPHRAGMATIC VAGAL TRUNKS AND THEIR ABDOMINAL BRANCHES. *(E.)* Kemp, D. R. (no affil.). *Aust. N.Z. J. Surg.* 43(3):288-294, 1973.

The supradiaphragmatic vagus and its abdominal branches were subjected to fiber counts in normal dogs and in dogs that had undergone proximal vagal sections resulting in fiber degeneration. In normal dogs, both vagal trunks, just before entering the abdomen, are composed of approximately equal numbers of fibers. The mean fiber count for the ventral trunk was 12,500 and for the dorsal trunk 13,233. Overall, it appears that 50% of the vagal fibers entering the abdomen, both efferent and afferent, are destined to supply the acid-bearing portion of the stomach. After extracranial supranodose unilateral vagotomy, the mean total fiber count in the abdominal vagal trunks was 24,655. This figure is slightly less than that obtained for the intact trunks (26,000 fibers) and represents a 50% loss of efferent fibers from the total vagal complement. The mean total fiber content of the abdominal trunks after unilateral infranodose vagotomy was 13,083 fibers. A mean total of 2250 fibers remained following bilateral vagotomy. The results suggest that there is no gross alteration in the functional distribution of fibers as branching occurs.

4134 SCANNING ELECTRON MICROSCOPY OF EXTRAHEPATIC BILIARY OBSTRUCTION. *(E.)* Compagno, J.; Grisham, J. W. (Washington Univ. Sch. Med., St. Louis, Mo.). *Arch. Pathol.* 97(6):348-351, 1974.

Scanning electron microscopy was used to evaluate the surface structure of rat liver parenchyma, both in normal rats and for 1 to 7 days after ligation of the common bile duct. After *in situ* fixation with 2.5% phosphate-buffered glutaraldehyde, examination by scanning electron microscopy showed flattening, progressive dilatation, and formation of sacculations and smooth-walled diverticula in bile canaliculi that were not seen in the normal liver. The canaliculi developed tortuosities, dilations, and angulations with prolonged obstruction. These changes usually occurred within 72-96 hr after duct ligation and did not progress significantly after day 4. Other than shearing artifacts caused by digital fracturing and seen at portal tracts and at the edges of endothelial cells, no evidence of artifacts caused by surface tension or evaporative forces was observed in these preparations. These results suggest that scanning electron microscopy is a useful adjunct for the study of normal and pathologic surface anatomy.

4135 ULTRASTRUCTURAL CHANGES IN THE LIVER OF BABOONS FOLLOWING LEAD AND ENDOTOXIN ADMINISTRATION. *(E.)* Hoffmann, E. O.; Di Luzio, N. R.; Holper, K.; Brettschneider, L.; Coover, J. (Louisiana State Univ. Med. Ctr., New Orleans). *Lab. Invest.* 30(3):311-319, 1974.

Adult baboons (*Papio papio*) received i.v. injections of either lead acetate (25 mg/kg) or *Escherichia coli* endotoxin (0.07 mg/kg), or both substances combined. The administration of lead or endotoxin alone did not result in any deaths, but simultaneous injection of both substances resulted in a 100% mortality rate. Ultrastructural changes in the group which received lead were characterized by vacuolization of some Kupffer cells and the presence of finely granular, electron-dense material. A very small number of parenchymal cells displayed degenerative changes. The endotoxin group had few fibrin deposits in the sinusoids and degenerative changes in a small proportion of both Kupffer and parenchymal cells. The morphologic changes produced by the combination of lead and endotoxin were marked and consisted of large deposits of fibrin and the presence of cellular debris and inflammatory cells in the sinusoids. Vacuolization and autophagocytosis of Kupffer and parenchymal cells, as well as necrosis and formation of large multivesicular bodies and fat droplets, occurred in parenchymal cells. The space of Disse was frequently obliterated by protein deposits. A finely granular, electron-dense material was also observed within the liver cells and sinusoids. Incipient lead inclusion bodies were present in the nucleus of Kupffer and parenchymal cells. Further experiments will be required to determine whether lead and endotoxin have a similar synergistic effect in man.

4136 ACTION OF PHENOBARBITAL ON THE ULTRASTRUCTURE AND THE ENZYMATIC ACTIVITY OF THE MOUSE INTESTINE AND THE MOUSE LIVER. *(E.)* Menard, D.; Berteloot, A.; Hugon, J. S. (Med. Ctr., Univ. Sherbrooke, Canada). *Histochemistry* 38(3):241-252, 1974.

The fine structure and the cytochemical activity of the liver, duodenum, and jejunum of 5-month-old Swiss ICR male mice were studied after phenobarbital treatment (100 mg/kg i.p. for 1-7 days). Proliferation of the smooth endoplasmic reticulum was observed in the centrilobular hepatocytes after 3 injections of phenobarbital and in the apical cells of the intestinal villi after 1 injection. In the liver, glucose-6-phosphatase activity remained localized in all the cisternae of the endoplasmic reticulum and in the nuclear envelope. Specific activities of glucose-6-phosphatase reached minimal values in the liver after 3 injections and in the duodenum and jejunum after 1 injection. Thereafter, values increased to normal levels in the liver and duodenum, despite daily injections of phenobarbital. In the jejunum, however, specific activities remained low. In contrast, alkaline phosphatase activities remained unchanged in the duodenum but increased in the jejunum. However, activities in the jejunum remained lower than those in the duodenum.

4137 STEREOLOGICAL ANALYSIS OF THE GUINEA PIG PANCREAS. I. ANALYTICAL MODEL AND QUANTITATIVE DESCRIPTION OF NONSTIMULATED PANCREATIC EXOCRINE CELLS. *(E.)* Bolender, R. P. (Dept. Anat., Univ. Berne, Switzerland). *J. Cell Biol.* 61(2): 269-287, 1974.

A stereological model which provides detailed quantitative information on the structure of the fasted, nonstimulated gland has been developed for the guinea pig pancreas. The model consists of morphologically defined space and membrane compartments which were used to describe the general composition of the tissue and the specific components of exocrine cells. The results are presented, where appropriate, relative to 1 cm^3 of pancreas, 1 cm^3 of exocrine cell cytoplasm, and to the volume of an average exocrine cell. The exocrine cells, accounting for 82% of the pancreas volume, consisted of 54% cytoplasmic matrix, 22% rough-surfaced endoplasmic reticulum, 8.3% nuclei, 8.1% mitochondria, 6.4% zymogen granules, and 0.7% condensing vacuoles. Their total membrane surface area was distributed as follows: 60% rough-surfaced endoplasmic reticulum, 21% mitochondria, 9.9% Golgi apparatus, 4.8% plasma membranes, 2.6% zymogen granules, 1.8% plasma membrane vesicles, and 0.4% condensing vacuoles.

4138 COMPARATIVE MORPHOLOGICAL AND HISTOAUTORADIOGRAPHIC STUDY OF MULTIPLE EXPERIMENTAL INTESTINAL TUMOURS. *(E.)* Pozharisski, K. M.; Klimashevski, V. F. (N. N. Petrov Res. Inst. Oncol., Leningrad, USSR). *Exp. Pathol. (Jena)* 9(1-2):88-98, 1974.

1,2-dimethylhydrazine (7-40 mg/kg) administered both p.o. and parenterally induced multiple primary tumors in different parts of rat intestine. These neoplasms were of different histological patterns, i.e., tubular, papillary, mucus-secreting and scirrhous adenocarcinomas, and mucous and signet-ring cell carcinomas. Histoautoradiographic study with simultaneous administration of ^{3}H- thymidine and colchicine revealed that individual tumors had different parameters of cell population kinetics. The labeling index for invasive adenocarcinomas of colon varied from 15.5 to 55.2% while the mitotic index, the duration of G$_2$- and S-phases, and generation time ranged between 1.8 and 8.9%, 0.3 and 2.88 hr, 13.8 and 54.5 hr, and 24.5 and 117 hr, resp. The autoradiographic investigation showed that proliferative activity was highest in signet-ring cell carcinomas and lowest in mucinous cancers. Adenocarcinomas had intermediate activity. Differences in cell cycle parameters in neoplasms of the same and of different histological structure are probably due to the trophic conditions of tumor cells. The differences in the parameters of cell population kinetics of tumors of both one histological type and various ones suggest the different times of their appearance and different rates of their growth.

4139 IMMUNOFLUORESCENT LOCALIZATION OF GASTRIN IN RABBIT ANTROPYLORIC MUCOSA TO ARGYROPHIL CELLS EXHIBITING FORMALDEHYDE-OZONE-INDUCED FLUORESCENCE. *(E.)* Larsson, L. I.; Sundler, F.; Hakanson, R.; Rehfeld, J. F.; Stadil, F. (Univ. Lund, Sweden). *Histochemie* 37(1):81-87, 1973.

The cellular localization of gastrin in the rabbit pyloric antrum was established by immunofluorescence. Gastrin was found in the cytoplasm of a large number of epithelial cells in the pyloric gland area. The immunofluorescent cells were characteristically distributed in the basal half of the mucosa. Similar cells were also found scattered in the mucosa of the duodenal bulb, but were far fewer than in the pyloric gland area. The gastrin cell was argyrophil with the Grimelius technique and was identical with a previously described cell type that emits fluorescence upon combined formaldehyde-ozone treatment, a feature that has been interpreted as indicating storage of peptides with NH$_2$-terminal tryptophan. The identity of the peptide and its relation to gastrin is unknown.

4140 TRUNCAL SUBDIAPHRAGMATIC VAGOTOMY AND ITS EFFECTS ON THE RAT PANCREAS AND LIVER IN LONG-TERM EXPERIMENTS. *(Ger.)* Kothe, W.; Albert, H.; Graetz, H.; Nowotny, K. (Surg. Clin., Karl Marx Univ., Leipzig, Germany). *Zentralbl. Chir.* 98(31): 1111-1115, 1973.

4141 AN ULTRASTRUCTURAL STUDY OF THE ETHANOL-INDUCED INHIBITION OF DUODENAL CALCIUM TRANSPORT. *(E.)* Sampson, H. W.; Krawitt, E. L. (Baylor Coll. Dentistry, Dallas, Texas). *Gastroenterology* 66(4):770, 1974.

4142 ENDOSCOPIC BIOPSIES OF NORMAL DUODENAL MUCOSA. *(E.)* Korn, E. R.; Foroozan, P. (Scripps Clin. Res. Fdn., La Jolla, Calif.). *Gastroenterology* 66(4):815, 1974.

4143 ULTRASTRUCTURAL AND ENZYMIC CHARACTERISTICS OF INTESTINAL MICROVILLOUS ROUND BODIES. *(E.)* Humphrey, C. D.; Pittman, F. E.; Pittman, J. C. (Med. Univ. South Carolina, Charleston). *Gastroenterology* 66(4):847, 1974.

4144 EXPERIMENTAL CHRONIC ENDOGENOUS HYPERGASTRINISM ACCOMPANIED BY INCREASED GASTRIN CELL DENSITY. *(E.)* Lehy, T.; Constantin-Voillemot, N.; Dubrasquet, M.; Bonfils, S. (Bichat Hosp., Paris, France). *Gastroenterology* 66(4):850, 1974.

4145 LIVER ULTRASTRUCTURE IN ABETALIPOPROTEINEMIA AND HYPOBETALIPOPROTEINEMIA. *(E.)* Partin, J. C.; Partin, J. S.; Schubert, W. K. (no affil). *J. Clin. Invest.* 53(6):58a, 1974.

4146 MORPHOLOGICAL AND HISTOCHEMICAL STUDY ON THE MAJOR SALIVARY GLANDS OF MICE INJECTED WITH DACTINOMYCIN. *(E.)* Ribeiro, M. C. L.; Fava-De-Moraes, F. (Biomed. Sci. Inst., Univ. Sao Paulo, Brazil). *Acta Anat.* 87(2):248-260, 1974.

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4147 ELECTRON MICROSCOPE STUDIES OF THE SMOOTH MUSCULATURE OF THE HUMAN STOMACH. LINKAGES BETWEEN MUSCLE CELLS AND THEIR RELATIONSHIP TO COLLAGEN FIBERS. *(Ger.)* Konig, Jr., B. (Inst. Anat., Univ. Campinas, Brazil). *Anat. Anz.* 135(1/2): 47-55, 1974.

4148 UTILIZATION OF THE SAME SPECIMEN OF GASTROINTESTINAL TISSUE FOR BOTH TRANSMISSION AND SCANNING ELECTRON MICROSCOPY. *(E.)* Winborn, W. B.; Guerrero, D. L. (Univ. Texas Health Sci. Ctr., San Antonio). *Gastroenterology* 66(4):871, 1974.

4149 HISTOCHEMICAL CHARACTERISTICS OF THE SMALL INTESTINE MUCOSA UNDER CONDITIONS OF FUNCTIONAL OVERLOADING. *(Rus.)* Kostromin, A. S. (Kiev Sci. Res. Inst. Clin. Exp. Surg., USSR). *Vrach. Delo* (4):36-39, 1974.

See also 4231, 4237, 4311, 4312, 4347, 4348, 4713.

ABSORPTION-EXCRETION-TRANSPORT

4150 PROTEIN UPTAKE BY THE INTESTINE: EVIDENCE FOR ABSORPTION OF INTACT MACROMOLECULES. *(E.)* Warshaw, A. L.; Walker, W. A.; Isselbacher, K. J. (Massachusetts Gen. Hosp., Boston). *Gastroenterology* 66(5):987-992, 1974.

The ability of the mature small intestine to absorb intact protein was studied in adult male albino Charles River rats prepared with duodenal cannulas, mesenteric lymph fistulae, and portal vein cannulas. After infusion of tritium labeled bovine serum albumin (0.5 - 500 mg/kg) into the duodenum, approximately 2% of the albumin was transmitted in macromolecular form into the lymph and blood; the amount of albumin transmitted was directly proportional to the amount administered. The molecular weight of the absorbed macromolecule exceeded 50,000 by Sephadex gel filtration. Absorbed protein was immunologically identified as bovine serum albumin on Ouchterlony plates with monospecific rabbit antibovine serum albumin. The findings offer evidence for the concept that intact protein can transverse the mature intestinal epithelium under physiologic conditions. The significance of such absorption on intact protein is not yet determined. A possible connection in the pathogenesis of cholera, botulism, and inflammatory bowel disease has been postulated.

4151 CALCIUM ABSORPTION OR SECRETION BY RAT ILEUM IN VITRO: EFFECTS OF DIETARY CALCIUM INTAKE. *(E.)* Walling, M. W.; Kimberg, D. V. (Beth Israel Hosp., Boston, Mass.). *Am. J. Physiol.* 226(5):1124-1130, 1974.

Ileum from rats given a 2.0%, high-calcium diet as weanlings, actively secretes calcium into the gut lumen throughout life, while ileum from animals similarly raised on a 0.02%, low-calcium diet actively absorbs calcium only during growth. The kinetics of ileal calcium fluxes suggest that the effect of the low-calcium diet may result in the appearance of a saturable process in both mucosal-to-serosal flux and initial mucosal uptake rates. The calcium-absorptive capacity of the ileum also appears to be increased by a low-calcium diet. No correlation was observed between the direction of net calcium flux (absorption or secretion) and serum calcium levels. Regulation of the direction of net calcium flux appears to be achieved by changes in mucosal-to-serosal flux, rather than by changes in the flux from serosa to mucosa. Active ileal calcium secretion apparently occurs at any time in life when the animal is in an "adequately positive" calcium balance, and active ileal absorption can occur whenever there is a sufficient metabolic need for calcium.

4152 INHIBITION OF ACTIVE HEXOSE AND AMINO ACID TRANSPORT BY CONJUGATED BILE SALTS IN RAT ILEUM. *(E.)* Caspary, W. F. (Dept. Med., Univ. Gottingen, Germany). *Eur. J. Clin. Invest.* 4(1):17-24, 1974.

The effect of conjugated trihydroxy bile salts, taurocholate, glycocholate, and deoxycholate on the tissue uptake and mucosal-to-serosal transfer of actively transported hexoses and amino acids has been examined *in vitro* in the ileum and jejunum of female Wistar rats. Conjugated trihydroxy bile salts and deoxycholate markedly inhibited active transport of hexoses and amino acids in the ileum, whereas deoxycholate alone was inhibitory in the jejunum. The inhibitory effect of tauro- and glycocholate increased with incubation time. It persisted after the tissue had been washed and reincubated with hexoses in a bile salt free medium and could be observed with only 2 x 10^{-4} M taurocholate. Taurocholate increased the transmural potential difference in the ileum but did not affect the potential difference in the jejunum. Preincubation of the ileum with taurocholate depressed subsequent glucose-induced increases in the potential difference. In the jejunum, however, taurocholate did not affect glucose-induced increases in the potential difference. It is concluded that conjugated trihydroxy bile salts have to enter intestinal mucosal epithelial cells to an appreciable extent in order to affect other active, energy-requiring transport systems in rat small intestine. Previous reports that conjugated bile salts failed to inhibit active transport of hexoses and amino acids are understandable since only jejunal transport had been examined.

4153 TRANSPORT OF BOVINE CHYMOTRYPSINOGEN INTO RABBIT PANCREATIC CELLS. *(E.)* Liebow, C.; Rothman, S. S. (Dept. Physiol., Univ. California, San Francisco). *Am. J. Physiol.* 226(5):1077-1081, 1974.

Chymotrypsinogen uptake was measured into slices of rabbit pancreas incubated in bovine ^{3}H-chymotrypsinogen and ^{131}I-albumin. Chymotrypsinogen uptake was 16 times greater than that for albumin. ^{3}H-chymotrypsinogen was not readily "chased" by washing in cold chymotrypsinogen. Exogenous enzyme was distributed within the cell like endogenous enzyme, i.e., zymogen granules had the highest specific radioactivity. Enzyme entered the cytoplasm more rapidly than the zymogen granules. After 60 min, both fractions approached tracer equilibration while mitochondrial and microsomal fractions were still far below bath specific radioactivity, suggesting that these enzyme pools exchanged relatively freely with media. The existence of enzyme equilibrium between bath-cytoplasm-zymogen granules suggests bidirectional processes, at least one of which appears to involve the transport of proteins across plasma membrane by nonexocytotic mechanisms.

4154 BRUSH-BORDER PROCESSES AND TRANSEPITHELIAL Na AND Cl TRANSPORT BY RABBIT ILEUM. *(E.)* Nellans, H. N.; Frizzell, R. A.; Schultz, S. G. (Univ. Pittsburgh Sch. of Med., Pa.). *Am. J. Physiol.* 226(5):1131-1141, 1974.

The effects of Cl^- replacement on bidirectional Na^+ fluxes and Na^+ replacement on bidirectional Cl^- fluxes across short-circuited, stripped rabbit ileum were determined under control conditions and in the presence of 10 mM theophylline. Under control conditions, both Na^+ and Cl^- are actively absorbed. Replacement of Cl^- with $SO_4^=$ reduces but does not abolish active Na^+ absorption. Replacement of Na^+ with choline abolished active Cl^- absorption. Theophylline markedly increased intracellular cyclic adenosine monophosphate levels and at the same time abolished net Na^+ movements and elicited active Cl^- secretion. In the presence of theophylline, replacement of Na^+ with choline abolished active Cl^- secretion, and replacement of Cl^- with $SO_4^=$ restored active Na^+ absorption. These results are consistent with the presence of a neutral, reversible NaCl transport mechanism at the mucosal membranes, which is capable of mediating NaCl influx as well as NaCl efflux across these membranes, together with a Cl^--independent, theophylline-insensitive Na^+ influx mechanism. The effects of theophylline can be explained by postulating that elevated intracellular cyclic adenosine monophosphate levels inhibit NaCl influx *via* the coupled mechanism and unmask the neutral NaCl efflux process. Studies on the serosa-to-mucosa unidirectional flux of Na^+ as a function of the transepithelial potential difference are consistent with the notion that this movement is attributable to strict ionic diffusion in the presence and absence of theophylline and is probably confined to the extracellular shunt pathway.

4155 SODIUM ION TRANSPORT IN ISOLATED INTESTINAL EPITHELIAL CELLS: THE EFFECT OF ACTIVELY TRANSPORTED SUGARS ON SODIUM ION EFFLUX. *(E.)* Gall, D. G.; Butler, D. G.; Tepperman, F.; Hamilton, J. R. (Hosp. Sick Children, Toronto, Canada). *Biochim. Biophys. Acta* 339(3):291-302, 1974.

The effect of actively transported sugars on Na^+ efflux from isolated rat jejunal epithelial cells was examined to evaluate the mechanism by which actively transported nonelectrolytes stimulate Na^+ absorption. Glucose, galactose, and 3-*O*-methylglucose, sugars known to be actively transported by the small intestine, stimulate total Na^+ efflux from isolated epithelial cells. This stimulation results from an increase of active Na^+ transport, since it is inhibited by ouabain. Glucose stimulation is significantly greater than that produced by galactose or 3-*O*-methylglucose. 2-Deoxyglucose, a sugar that is not actively transported, has no effect on total Na^+ efflux from isolated cells. Phlorizin, which has no effect on Na^+ efflux in a sugar-free medium, completely abolishes the effect of galactose. These findings support the hypothesis that the increase in intestinal absorption of Na^+ in the presence of actively transported nonelectrolytes occurs by a transcellular route; and are consistent with the ion-gradient model. The results are not compatible with the direct energy-coupling model.

4156 FUNCTIONAL CHARACTERIZATION OF DIPEPTIDE TRANSPORT SYSTEM IN HUMAN JEJUNUM. *(E.)* Adibi, S. A.; Soleimanpour, M. R. (Montefiore Hosp., Pittsburgh, Pa.). *J. Clin. Invest.* 53(5):1368-1374, 1974.

Jejunal segments (15 cm) from 18 human volunteers were perfused with test solutions containing varying amounts of glycylglycine, glycylleucine, glycine, leucine, glycylglycine with leucine or glycine, glycylglycine with glycylleucine, or glycylleucine with an equimolar mixture of free glycine and leucine. Jejunal absorption rates of both glycylglycine and glycylleucine followed the kinetics of a saturable process. The transport kinetics of dipeptides were characterized by higher V_{max} values than those of free amino acids. While jejunal absorption rates of glycylglycine were not significantly affected by free leucine or free glycine, they were competitively inhibited by glycylleucine. The jejunal absorption rate of glycylleucine was not significantly altered by an equimolar mixture of free glycine and leucine. The selective absorption of dipeptides was investigated by infusing 3 equimolar mixtures, each containing 2 different dipeptides. Among the 3 dipeptides examined, glycylgycine was the least absorbed. There was no significant difference between the absorption of glycylleucine and leucylglycine. The data suggest that dipeptide absorption is mediated by a carrier which is not shared with free neutral amino acids. Both COOH- and NH_2-terminal amino acids are important in determining the characteristics of dipeptide absorption.

4157 THE FAILURE OF INDOMETHACIN TO MODIFY THE RESPONSE OF CAT SMALL INTESTINE TO CHOLERA ENTEROTOXIN. *(E.)* Dlugolecka, M. J. (Dept. Pharmacol., Univ. Edinburgh, Scotland). *Pol. J. Pharmacol. Pharm.* 26(1-2):93-100, 1974.

The effect of 2 prostaglandin synthesis inhibitors and anti-inflammatory drugs were studied in a series of 21 cats in which the terminal small intestine was challenged with cholera toxin. Neither indomethacin (10, 50, and 100 mg/kg i.v., 600 μg/loop administered locally) nor aspirin (25 mg/kg i.v.) was able to modify fluid secretion in toxin-treated loops. It is concluded that prostaglandins are not likely to be mediators of the fluid loss observed in the terminal small intestine.

4158 CALCITONIN AND INTESTINAL CALCIUM ABSORPTION. *(E.)* Swaminathan, R.; Ker, J.; Care, A. D. (Dept. Animal Physiol., Univ. Leeds, England). *J. Endocrinol.* 61(1):83-94, 1974.

The effect of calcitonin on small intestinal calcium absorption was studied using Thiry-Vella loops in one intact sheep, one intact pig, and three parathyroidectomized pigs. After recirculating through the loop a known volume of a solution containing calcium and polyethylene glycol 4000, net calcium absorption rate was measured. Calcitonin was infused i.v. and its effect on the net calcium absorption rate was measured. An initial rise in net calcium absorption associated with hypocalcemia, followed by a marked reduction in calcium absorption was noted after relatively high doses of calcitonin, 10 mμ/min/kg, were infused for up to 45 hr. The increase in the net absorption rate was either not observed or was less marked, when smaller doses of calcitonin, 0.5 mμ/min/kg, were infused for 100 hr. However, there was a significant reduction in net calcium absorption 2 days after the calcitonin infusion was stopped. Both intact and parathyroidectomized animals showed a reduction in net calcium absorption rate. In an experiment in which the true absorption rate of calcium from lumen to blood was measured using ^{47}Ca, a reduction in unidirectional transfer of calcium from lumen to blood was noted 2 days after the calcitonin infusion stopped. It was concluded that i.v. infusion of calcitonin for prolonged periods of time reduced absorption of calcium from the intestine, perhaps by inhibiting conversion of 25 hydroxycholecalciferol to 1,25-dihydroxycholecalciferol, thus leading to a reduction in intestinal calcium binding protein. This may indicate a role for calcitonin in calcium homeostasis during the ingestion of a high calcium diet.

MOTILITY

4186 ELECTRICAL AND MOTOR ACTIVITY OF HUMAN AND DOG COLON IN VITRO. *(E.)* Vanasin, B.; Ustach, T. J.; Schuster, M. M. (Baltimore City Hosp., Md.). *Johns Hopkins Med. J.* 134(4):201-210, 1974. 134(4):201-210, 1974.

Simultaneous recordings of electrical and motor activity from resected specimens of human and canine colon demonstrated the sporadic nature of both types of activity. In the human colon, there were two electrical slow wave gradients: a gradient of decreasing frequency from the cecum to the transverse colon; and gradient of increasing frequency from the transverse colon to the distal rectum. The electrical activity originated in the taenia coli and spread to the intervening longitudinal and circular muscle. In the rectum, which contains no taenia, the electrical activity began in the longitudinal muscle and spread to the circular muscle. In the dog, whose entire colon lacks taenia coli, there was a single gradient of increasing frequency in a cephalocaudal direction; the electrical activity originated in the longitudinal muscle and spread to the circular muscle. Differences between the small intestinal and colonic activities can be correlated with the different embryological origins, innervations, and functions of these two organs.

4187 EFFECT OF INTRADUODENAL ADMINISTRATION OF ESSENTIAL AMINO ACIDS AND SODIUM OLEATE ON MOTOR ACTIVITY OF THE SIGMOID COLON. *(E.)*

Meshkinpour, H.; Dinoso, Jr., V. P.; Lorber, S. H. (Temple Univ. Health Sci. Ctr., Philadelphia, Pa.). *Gastroenterology* 66(3):373-377, 1974.

The effects of the intraduodenal administration of solutions of essential amino acids and 5% sodium oleate on the motor activity of the sigmoid colon were studied in 11 normal subjects and in one patient with a previous antrectomy. A marked increase in motor activity was observed during the administration of both solutions in all subjects. The i.v. perfusion of pentagastrin (0.6 μg/kg/hour) in six subjects did not significantly influence the motor activity of the sigmoid colon. The data suggest that the increased motor activity in the sigmoid colon which is observed in response to exposure of the duodenum to essential amino acids and sodium oleate could result from the release of endogenous cholecystokinin.

4188 THE ACTION OF CHOLECYSTOKININ AND RELATED PEPTIDES ON GUINEA PIG SMALL INTESTINE.

(E.) Yau, W. M.; Makhlouf, G. M.; Edwards, L. E.; Farrar, J. T. (Med. Coll. Virginia, Richmond). *Can. J. Physiol. Pharmacol.* 52(2):298-303, 1974.
col. 52(2):298-303, 1974.

The mode of action of cholecystokinin (CCK), cerulein, pentagastrin, and an octapeptide fragment of CCK on isolated guinea pig muscle was investigated, and the relative potencies of the four peptides compared. On a molar basis, octapeptide-CCK and cerulein were about twice as potent as CCK, whereas pentagastrin and Urecholine were 23 and 46 times less potent, respectively. Scopolamine (6.84×10^{-1} M) inhibited the response to all four peptides relatively less than the response to Urecholine. Tetrodoxin (0.1 μg/ml) inhibited the response to all peptides by 91%. The effect of these peptides on ileal muscle was largely mediated by cholinergic mechanisms. However, it was not clear whether the effect resulted solely from the release of acetylcholine by nerve endings or from the participation of acetylcholine mainly as a synergist of the peptides' action on smooth muscle fibers.

4189 DIFFERENTIATION OF THE CONTRACTILE EFFECTS OF PROSTAGLANDIN E_2 AND THE C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ IN ISOLATED GUINEA-PIG GALLBLADDER. *(E.)*

Andersson, K. E.; Hedner, P.; Persson, C. G. A. (Dept. Pharmacol., Univ. Lund, Sweden). *Acta Physiol. Scand.* 90(4):657-663, 1974.

In the isolated guinea-pig gallbladder, contractions were induced by acetylcholine, the C-terminal octapeptide of cholecystokinin, prostaglandin E_2, and the prostaglandin precursor arachidonic acid. The effects on these contractions induced by the inhibitor of the prostaglandin synthesis, indomethacin, and of the prostaglandin antagonists, polyphoretin phosphate, and SC 19220 [1-acetyl-2-(8-chloro-10,11-dihydrobenz(b,f)(1,4)oxazepine-10-carbonyl)hydrazine], were investigated. Indomethacin (0.5 μg/ml) inhibited the response to arachidonic acid but did not appreciably affect contractions induced by the other agents. Indomethacin (10 μg/ml) reduced the responses to all the agonists, probably due to a non-specific depressive effect. Polyphloretin phosphate (1-10 μg/ml) had no effects on the elicited contractions. In concentrations of 100-400 μg/ml, polyphloretin phosphate caused a transient contraction in gallbladder strips and reduced the response to the agonists used. SC 19220 (2 and 8 μg/ml) selectively inhibited the responses of arachidonic acid and prostaglandin E_2 but had little or no effect on contractions induced by acetylcholine and the C-terminal octapeptide. Inhibition of the response to prostaglandin E_2 could be overcome by increasing the bath concentration of the prostaglandin 5-100-fold. It is concluded that local synthesis and release of prostaglandins play no essential role in mediation of the contractile effect of the C-terminal octapeptide of cholecystokinin in guinea-pig gallbladder.

4190 THE EFFECTS OF PROSTAGLANDIN A_2 (PGA_2) ON THE GUINEA-PIG ISOLATED ILEUM. *(E.)*

Straczkowski, W.; Kalicinski, A.; Nowak, W.; Malofiejew, M. (Med. Acad., Bialystok, Poland). *Pol. J. Pharmacol. Pharm.* 26(1-2):253-255, 1974.

Segments of isolated guinea-pig ileum were suspended in an organ bath of oxygenated Tyrode solution containing various concentrations of prostaglandin A_2 at 37 C. Above threshold doses of 25-50 ng/ml, prostaglandin A_2 induced transient contraction of isolated guinea-pig ileum, followed by an increase in its tonus. Submaximal contractions were proportional to the logarithm of the dose of prostaglandin A_2. Addition of atropine (2×10^{-7}g/ml), antazoline (10^{-7}g/ml), or lysergic acid diethylamide (10^{-8}g/ml) to the bath had no effect on the action of prostaglandin A_2. Therefore, the effect of prostaglandin A_2 does not appear to be mediated by acetylcholine, histamine, or serotonin and the corresponding receptors are not involved. Since bradykinin-induced contractions of the ileum were enhanced by incubation with prostaglandin A_2, one of the physiological functions of the prostaglandins may be to modify the effects of some biologically active polypeptides.

4191 EFFECT OF GASTRIC DISTENTION ON MOTILITY AND PLASMA GASTRIN CONCENTRATION BEFORE

AND AFTER SECRETIN ADMINISTRATION. *(E.)* Schrumpf, E.; Stadaas, J. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(2):119-122, 1974.

Gastric motility and plasma gastrin concentrations were measured in 6 healthy adults before and after stepwise distention of the stomach and after the i.v. infusion of secretin (3 U/kg/hr in 0.9% NaCl). Plasma gastrin levels were not significantly changed by distention or secretin administration, but gastric motility was significantly increased by increasing distention. The contractile activity consisted predominantly of type II pressure peaks, but slow pressure waves resembling type III gastric pressure waves were also seen. The basal pressure was essentially unchanged by distention. Administration of secretin caused pronounced inhibition of motor activity in the stomach. Rhythmic contractions completely disappeared, leaving only basal pressure recordings which showed insignificant variations with volume increments and secretin infusion. Thus, the motility-reducing effect of secretin is independent of changes in the plasma gastrin level.

4192 THE EFFECTS OF GRADED DOSES OF C-TERMINAL OCTAPEPTIDE OF CHOLECYSTOKININ ON SMALL INTESTINAL TRANSIT TIME IN MAN. *(E.)* Levant, J. A.; Kun, T. L.; Jachna, J.; Sturdevant, R. A. L.; Isenberg, J. I. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Am. J. Dig. Dis.* 19(3):207-209, 1974.

In 6 male subjects without gastrointestinal disease, graded i.v. doses of the C-terminal octapeptide of cholecystokinin produced graded decreases in small intestinal transit time. Mean transit time decreased from a control value of 130 minutes after 0.15 M NaCl to 81, 65, and 19 min after 5, 10, and 20 ng/kg resp. of the octapeptide. Side effects (nausea and abdominal discomfort) were minimal and transient, lasting less than 3 min, and the radiographic appearance of the small intestine remained unchanged.

4193 THE EFFECT ON GASTRIC EMPTYING OF TEST MEALS WITH VARIOUS FAT AND OSMOLAR CONCENTRATION. *(E.)* Moberg, S.; Carlberger, G. (St. Erik's Hosp., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(1):29-32, 1974.

The gastric emptying of fluid meals with various fat and osmolar concentrations was studied in healthy volunteers. The emptying pattern was composed of an initial phase characterized by a rapid rate, followed by a prolonged second phase having an approximately constant rate and lasting until the stomach is almost empty. When fat-free meals were given, osmotic load on the duodenum decreased the emptying rate during the initial phase. On the other hand, fat in the meals decreased the emptying rate during the prolonged phase.

4194 THE INFLUENCE OF LONG-TERM INTERMITTENT EXPOSURES TO HYPOXIA ON GASTRIC EMPTYING TIME IN RATS. *(E.)* Fang, H. S.; Chen, C. F. (Coll. Med., Natl. Taiwan Univ., Taipei, China). *Space Life Sci.* 4(3/4):335-337, 1973.

The effect of long-term intermittent exposures to hypoxia corresponding to an altitude of 18,000 feet on gastric emptying time was studied roentgenologically under normal oxygen tension. If male Long-Evans rats were exposed to hypoxia for 3 hr/day for 60 days, there was a marked decrease in gastric emptying time to an average of 0.86 hr, as compared to 1.29 hr in the control group. Long-term intermittent exposures might cause dominance of the parasympathetic nervous system in rats. If acclimatization-induced parasympathetic dominance does occur, it would be reasonable to expect an increased gastric motility resulting in an acceleration of the emptying time of the stomach.

4195 BLOCKADE BY PROSTAGLANDINS E_2 AND $F_{1\alpha}$ OF THE RESPONSE OF THE RABBIT ILEUM TO STIMULATION OF SYMPATHETIC NERVE AND ITS REVERSAL BY SOME ANTIHISTAMINES, DEXAMPHETAMINE AND METHYLPHENIDATE. *(E.)* Abdel-Aziz, A. (Dept. Pharm., Alexandria Univ., Egypt). *Eur. J. Pharmacol.* 25(2):226-230, 1974.

Prostaglandins E_2 and $F_{1\alpha}$, 0.05-1.0 µg/ml, blocked the inhibitory response of the isolated rabbit ileum to stimulation of periarterial nerve, without affecting responses to noradrenaline. The activity had a quick onset, did not increase much with time, and was more effective in blocking responses to stimulation of periarterial nerves at low frequencies (3, 5 and 7 shocks/sec) than at high frequencies (10, 20, and 60 shocks/sec). The effect was easily reversed by brief washing, by raising the calcium ion concentration, or by addition of dexamphetamine, methylphenidate, chlorpheniramine, or diphenhydramine, but not antazoline. Blockade by the prostaglandins most probably functions through reduction in the amount of the transmitter noradrenaline released.

4196 POTENTIATION OF THE BIPHASIC BRADYKININ RESPONSE OF THE GUINEA-PIG ILEUM. *(E.)* Hall, D. W. R.; Bonta, I. L. (Med. Fac., Erasmus Univ., Rotterdam, Netherlands). *Arch. Int. Pharmacodyn. Ther.* 207(2):361-372, 1974.

Cysteine, 2,3-dimercaptopropanol (BAL), α-thiol glycerol, and a synthetic pentapeptide (pyroglutamyllysyltryptophanylalanylproline, $BPP_{5\alpha}$) identical to one of the bradykinin potentiating factors isolated from the venom of *Bothrops Jararaca*, were examined for their effects on the bradykinin relaxation and contraction of the acetylcholine-contracted guinea pig ileum. Each of the substances potentiated bradykinin relaxation and contraction. Cysteine potentiated the bradykinin relaxation at concentrations between 10^{-5} to 10^{-4} M, while potentiation of the contraction occurred at 10^{-4} to 10^{-2} M. With BAL, potentiation of the relaxation response was observed between 10^{-6} to 10^{-5} M and potentiation of the contraction between 10^{-5} and 10^{-4} M. Both substances were up to 10 times more potent at potentiating the bradykinin relaxation than the contraction. There was no potency difference for relaxation and contraction with α-thiol glycerol or BPP$_{5\alpha}$. High concentrations of cysteine and BAL produced inconsistent effects, some potentiating and others reducing the bradykinin responses. High concentrations of cysteine (10^{-3} and 10^{-2}) potentiated acetylcholine contraction, while BAL (10^{-3}M) reduced it. It is suggested that there are 2 discrete receptors for bradykinin relaxation and contraction of the acetylcholine-contracted guinea-pig ileum.

4197 EFFECTS OF GYMNODINIUM BREVE TOXIN ON THE SMOOTH MUSCLE PREPARATION OF GUINEA-PIG ILEUM. *(E.)* Grunfeld, Y.; Spiegelstein, M. Y. (Israel Inst. Biol. Res., Ness-Ziona). *Br. J. Pharmacol.* 50(3):399-404, 1974.

SECRETION AND METABOLISM

Stomach

4209 EFFECT OF BILATERAL NEPHRECTOMY AND BILATERAL URETERAL LIGATION ON SERUM GASTRIN LEVELS IN THE RAT. *(E.)* Davidson, W. D.; Moore, T. C.; Shippey, W.; Conovaloff, A. J. (UCLA Sch. Med., Los Angeles, Calif.). *Gastroenterology* 66(4):522-525, 1974.

Serum gastrin activity was determined in male Sprague-

Dawley rats 48 hr after bilateral nephrectomy or bilateral ureteral ligation. Although both groups of rats became equally azotemic as indicated by their serum urea nitrogen levels, the serum gastrin levels were significantly elevated only in the animals which had sustained bilateral nephrectomies. These data indicate that hypergastrinemia due to renal failure is related to the loss of normal functioning renal mass and is not a result of the uremic state per se, and that the kidney is a major site of endogenous gastrin degradation in the rat.

4210 SECRETIN-INDUCED INHIBITION OF ACID SECRETION BEFORE AND AFTER VAGAL DENERVATION OF CANINE GASTRIC POUCHES.

(E.) Sjodin, L.; Miura, S. (Karolinska Inst., Stockholm, Sweden). *Scand. J. Gastroenterol.* 9(2):185-190, 1974. 185-190, 1974.

The inhibitory effect of secretin on pentagastrin-stimulated acid secretion was studied in mongrel dogs before and after transformation of vagally innervated fundic pouches (Pavlov type) into vagally denervated pouches (Heidenhain type). A high dose of secretin (3.0 U/kg/hr) profoundly inhibited ecretion from both types of pouches, whereas a wer dose (0.75 U/kg/hr) produced a significant ibition only in the Heidenhain pouches. Ure-ine reduced the inhibitory effect of secretin entagastrin-stimulated secretion from vagally vated pouches. When the fundic mucosa is vag- innervated, endogenous secretin appears to be of le or no importance as an inhibitor of gastric l secretion under physiological conditions. sin output evoked by combinations of penta-rin and secretin was low compared with that duced by a single infusion of Urecholine. The siological significance of the stimulatory effect ecretin on pepsin secretion remains to be est-shed.

11 THE EFFECT OF ENDOGENOUS SECRETIN AND CHOLECYSTOKININ ON PENTAGASTRIN-STIMULATED NNERVATED AND DENERVATED GASTRIC MUCOSA.

(E.) Dorighi, J. A.; Kaminski, D. L.; Willman, V. L. (St. Louis Univ. Sch. Med., Mo.). *Surgery* 75(5): 755-762, 1974.

The inhibition of pentagastrin-stimulated H^+ output by endogenous secretin and cholecystokinin (CCK) was evaluated in dogs with chronic gastric fistulas (innervated mucosa) and Heidenhain pouches (denervated mucosa). The release of endogenous secretin was stimulated by intraduodenal HCl, and endogenous CCK release was stimulated by intraduodenal elemental amino acids. The effectiveness of these methods in stimulating duodenal hormone release was confirmed in dogs with chronic pancreatic fistulas. Endogenous CCK produced no inhibition of pentagastrin-stimulated H^+ output from innervated or denervated mucosa. The intraduodenal amino acids produced a pancreatic response similar to but greater than that produced by 2 U/kg/hr of exogenous CCK; they did not inhibit the acid secretory response. Endogenous secretin was an effective enterogastrone which significantly inhibited the pentagastrin-stimulated H^+ response in innervated and denervated mucosa. The percent inhibition in the innervated mucosa was significantly greater at all intraduodenal H^+ doses than that produced in the denervated gastric mucosa. The results indicate that vagal section decreases the effectiveness of the duodenal enterogastrone.

4212 INCREASED GASTRIN RELEASE FOLLOWING PENETRATING CENTRAL NERVOUS SYSTEM INJURY.

(E.) Bowen, J. C.; Fleming, W. H.; Thompson, J. C. (Univ. Texas Med. Sch., Houston). *Surgery* 75(5):720-724, 1974.

Serum gastrin levels were determined by radioimmunoassay in 39 severely injured servicemen (18 to 30 years old) following either central nervous system (CNS) injury (16 patients) or non-CNS injury (23 patients). The serum gastrin concentrations were significantly elevated following CNS injury; five patients with either penetrating cerebral or spinal cord injuries had mean serum gastrin levels greater than 150 pg/ml. The serum gastrin levels were not increased in the non-CNS injury group. Ten of the non-CNS injury group and eight of the CNS injury group developed stress ulcers. Although the data suggest that there may be a difference in serum gastrin levels between those with and without stress ulcers in the CNS injury group, the findings were not statistically significant. A single patient in the CNS injury group with consistently high serum gastrin levels did not develop evidence of upper gastrointestinal bleeding. Thus, CNS-related stress ulcer may be a distinct pathophysiological entity from the non-CNS related stress ulcer, and the vagal release of gastrin may have clinical significance in humans after some forms of CNS injury.

4213 EFFECT OF ATROPINE ON PLASMA CONCENTRATION OF GASTRIN IN FASTING SUBJECTS.

(E.) Schrumpf, E.; Myren, J. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(2):123-125, 1974.

The effect of atropine (0.01 mg/kg, i.v.) on the basal gastrin level, acid secretion, and gastric pH was studied in five normal subjects and eight patients with achlorhydria and hypergastrinemia (two patients also had pernicious anemia). Following the s.c. injection of 6 µg/kg pentagastrin, the basal acid output (BAO) and maximal acid output (MAO) were zero in the patient group; the values were 3.5 + 1.0 and 24.3 + 2.4 mEq/h, respectively, in the normals. In the normal, there was a considerable decrease in the gastric output with a concomitant elevation in the pH of the gastric juice following atropine. Atropine had no effect on the basal gastrin level in the normals, but it caused a significant decrease in the basal gastrin level in the achlorhydric patients. The data suggest that there is a cholinergic influence on basal gastrin release in achlorhydric patients.

4214 EFFECTS OF CHOLECYSTOKININ, SECRETIN, 2-DEOXY-D-GLUCOSE AND INSULIN ON

ENTAGASTRIN-STIMULATED GASTRIC SECRETION IN ISTULA CHICKENS. *(E.)*

Burhol, P. G. (Ulleval osp., Oslo, Norway). *Scand. J. Gastroenterol.* (1):55-58, 1974.

he effect of cholecystokinin, secretin, 2-eoxy-D-glucose, and insulin on pentagastrin-timulated gastric secretion was studied in 14 istula chickens. Cholecystokinin elicited a rief rise in gastric water and H$^+$ secretion nd a sustained inhibition of pepsin secretion. ecretin also raised the gastric secretion f water temporarily, but caused insignificant hanges in gastric H$^+$ and pepsin secretion. -deoxy-D-glucose showed a late increase in he gastric water and H$^+$ secretion, but an nsignificant rise in pepsin secretion. Insulin aused a sustained inhibition not only of astric water and H$^+$ but of pepsin secretion s well. The significant inhibition of the entagastrin-stimulated pepsin secretion by nsulin and the lack of significant inhibition f basal pepsin secretion may be taken to uggest that a dual mechanism is involved in he gastric inhibition by insulin. It is herefore possible that insulin inhibits not nly by a direct action on the gastric transport f water and H$^+$, but also by interfering with he interaction between pentagastrin and the astric secretory cells, and so to produce an nhibiton of the pentagastrin-stimulated epsin secretion as well.

4215 DUODENAL ACIDIFICATION AND ANTRAL RELEASE OF GASTRIN. *(E.)*

Becker, . D.; Evans, J. C.; Reeder, D. D.; Thompson, J. . (Univ. Texas Med. Br., Galveston). *Arch. Surg.* 108(2):205-207, 1974.

The antrofundal junction of the stomach was clamped and the pylorus was ligated in 11 dogs. A 0.2% solution of acetylcholine chloride was allowed to flow into the antrum *via* a double-lumen catheter. In 5 dogs, the entire duodenum was perfused with an acid solution (pH 1.0) *via* catheters located in the duodenal bulb and just proximal to the ligament of Treitz. In the remaining 6 dogs, the proximal or distal portion of the duodenum was perfused with acid *via* catheters placed proximal and distal to the entrance of the main pancreatic duct. In both groups, irrigation of the antrum with acetylcholine increased the secretion of gastrin from the antrum. Acid perfusion of the entire duodenum promptly decreased the concentration of gastrin in the peripheral serum, while an increase in the pH of the perfusate to pH 7.0 resulted in a stepwise increase in the peripheral serum gastrin concentration. Acidification of the distal portion of the duodenum decreased gastrin levels in the antral venous outflow, as did acidification of the proximal portion of the duodenum. Thus, the inhibitory effect of duodenal acidification is at least partially explained by inhibition of gastrin release from the antrum.

4216 PROOF OF A PYLORO-OXYNTIC REFLEX FOR STIMULATION OF ACID SECRETION. *(E.)*

Debas, H. T.; Konturek, S. J.; Walsh, J. H.; Grossman, M. I. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Gastroenterology* 66(4):526-532, 1974.

In 7 dogs with innervated antral pouches, gastric fistulas, and Heidenhain pouches, acid secretion and serum gastrin (radioimmunoassay) were measured in response to distention of the antral pouch with 0.1 M NaHCO$_3$ or 0.1 M HCL at 0- 40-cm pressure. Distention with 0.1 M NaHCO$_3$ caused graded increases in the serum gastrin concentration and in the output of acid from both the gastric fistula and the Heidenhain pouch. Acidification of the antral pouch abolished the release of gastrin and secretion of acid from the Heidenhain pouch in response to distention, but did not abolish acid secretion from the gastric fistula. These results indicate that antral distention causes acid secretion by at least 2 mechanisms, only one of which is gastrin-dependent. Proof that the gastrin-independent mechanism is a pyloro-oxyntic reflex was obtained by showing that vagal denervation of the antral pouch completely abolished the response of the gastric fistula to distention of the antral pouch with acid. In addition to abolishing the pyloro-oxyntic reflex, antral vagal denervation also decreased the increment in serum gastrin caused by alkaline antral distention and increased the amount of acid secreted in response to any given increment in serum gastrin.

4217 THE EFFECT OF DRUGS INTERFERING WITH BIOGENIC AMINE METABOLISM ON BASAL GASTRIC SECRETION IN THE RAT. *(E.)*

Hano, J.; Bugajski, J.; Danek, L. (Dept. Pharmacol., Polish Acad. Sci., Krakow). *Pol. J. Pharmacol Pharm.* 25(6):537-549, 1973.

The influence of drugs that interfere with catecholamine and serotonin metabolism on basal gastric secretion was investigated in Wistar rats with chronic gastric fistulas. Exogenous dopamine suppressed the secretion of HCl and reduced pepsin output. Drugs that stabilize or increase the level of endogenous dopamine, e.g., α-methyl-p-tyrosine, disulfiram, and dimethyldithiocarbamate, also inhibited the secretion of HCl and pepsin. Inhibition of dopamine synthesis by administration of DL-α-methyl-p-tyrosine, however, unexpectedly failed to increase gastric secretion. Epinephrine reduced HCl output as much as 90%, mainly by decreasing the total volume of the gastric secretion, not by prevention of acid formation. Inhibitory actions of norepinephrine and isoproterenol were less that that of epinephrine. The inhibition of serotonin synthesis by p-chlorphenylalanine unexpectedly resulted in a strong reduction of gastric secretory activity, affecting the concentration and the total output of HCl and the content of pepsin. Nialamide reduced gastric secretion for a short time due, possibly, to a blockade of degradation mainly of dopamine. Imipramine, considered to increase catecholamines, also caused a decreased gastric secretion by all parameters studied.

4218 A HYPOCALCEMIC AGENT CONTAINING GASTRIN FROM DISTAL PORTIONS OF THE STOMACH IN MAN AND IN THE RAT. *(E.)*

Aliapoulios, M. A.; O'Neil, E. R.; Hori, C. G. (Harvard Med. Sch., Cambridge, Mass.). *Am. J. Surg.* 127(1):65-70, 1974.

Specimens of undiseased distal stomach from numerous Holtzman rats and from 25 consecutive patients were extracted. Extracts from rat stomach were assayed directly for hypocalcemic and gastrin activities, using thyrocalcitonin and pentagastrin, resp., as reference standards. Human stomach extracts were first lyophilized overnight to concentrate the active substances. For maximal effect in the assay for hypocalcemic activity, parathyroid hormone was first administered to assay rats in doses of 76 USP units 5 hours prior to the administration of the test extracts, and determination of serum calcium by EDTA titration was then carried out one quarter to two hours subsequent to injection of test extracts. Gastrin analysis of the extracts was performed by radioimmunoassay. The stomach from 6 week old rats on a normal diet caused significant hypocalcemia at doses of 200 mg, wet weight tissue extract, per assay rat at 1 or 2 hours or both after injection. The serum calcium differences from values of control rats untreated with stomach extract ranged from 0.37 to 1.21 mg/100 ml. An experiment testing the stomach of rats which had been fasted 20 hours demonstrated, however, no significant hypocalcemia with this same dose. Human stomach samples from 20 to 23 patients who were fasted prior to routine surgery for ulcer or cancer caused hypocalcemic responses at doses of 400 to 1,600 mg wet weight tissue extract 1 hour after injection in the test animals. Comparisons of stomach samples of the antrum in 8 patients divided into interior and exterior portions, indicated that the interior portion only in 5 patients and both portions in 2 patients caused significant hypocalcemia. Dialysis and ether extraction had no influence on the hypocalcemic effect of the extract. Analysis of extracts for gastrin content demonstrated the presence of 2,400 pg per 800 mg of wet weight human stomach and 2,000 pg per 200 mg of wet weight rat stomach extract. It is concluded that rat and human stomachs contain hypocalcemic substance(s) which may assist in regulating the serum calcium level at times of dietary calcium loads.

4219 THE EFFECTS OF THYROCALCITONIN ON GASTRIC ACID SECRETION IN INTACT AND THYROIDECTOMIZED THYROXIN-SUBSTITUTED GASTRIC FISTULA CATS. *(E.)*

Nordgren, C. E.; Nyhus, L. M.; Bombeck, C. T. (Univ. Illinois Coll. Med., Chicago). *Scand. J. Gastroenterol.* 9(1):103-109, 1974.

A single injection of thyrocalcitonin inhibited the stimulation of gastric secretion in the chronic fistula cat by injections of 2-deoxy-D-glucose or by constant infusion of pentagastrin and histamine in submaximal doses. Thyroidectomized as well as intact cats were studied and both groups showed similar responses to gastric stimulants. Thyrocalcitonin inhibited gastric secretion briefly in both groups, and there was an additional late inhibition of gastrin- and histamine-stimulated secretion in the thyroidectomized animals. A small dose of thyrocalcitonin did not inhibit pentagastrin-stimulated secretion in the thyroidectomized cats. No significant change in serum calcium concentration was observed. It was suggested, however, that the action of thyrocalcitonin which was observed may, nevertheless, have been due to the local reduction of available calcium necessary for the release or effect of acetylcholine in the secretory mechanism.

4220 EFFECT OF SEROTONIN AND ATROPINE ON RESERPINE-INDUCED GASTRIC SECRETION IN RATS. *(E.)*

Bugajski, J.; Hano, J.; Wantuch, C. (Dept. Pharmacol., Polish Acad. Sci., Krakow). *Pol. J. Pharmacol. Pharm.* 25(6):525-535, 1973.

The effect of serotonin and atropine on reserpine-induced gastric secretion and gastric ulcer development was investigated in Wistar rats with chronic gastric fistulas. Reserpine (2.5 or 5.0 mg/kg) 3 to 4 hr after injection, increased the HCl concentration but decreased the volume of secretion. Serotonin (1.0 or 5.0 mg/kg) or atropine (0.05 mg/kg), administered simultaneously with reserpine, 2.0 or 5.0 mg/kg, strongly reduced the output of HCl and pepsin. This was accomplished by reduction of volume of secretion, not concentration. Serotonin doubled, however, the number and diameter of reserpine-induced gastric ulcers, while atropine did not influence their development. The potentiating effect of serotonin was, therefore, independent of mechanisms of gastric acid and pepsin formation.

4221 STUDIES OF TWO TRITERPENOID COMPOUNDS ON THE GASTRIC MUCOSAL BARRIER: AN EXPERIMENTAL STUDY WITH CANINE HEIDENHAIN POUCHES. *(E.)*

Calcraft, B. J.; Rhodes, J.; Cross, S.; Hole, D.; Aubrey, A. (Univ. Hosp. Wales, Cardiff). *Am. J. Dig. Dis.* 19(3):243-252, 1974.

The protective action of 2 closely related triterpenes (lauroyl glycyrrhetinic acid and carbenoxolone) against mucosal damage by bile acid was examined in Heidenhain pouches of 4 dogs. The net fluxes of hydrogen and sodium ion were measured before, during and after exposure of the mucosa to a 10 mM bile acid solution at pH 2, and gastric transmucosal potential difference also was measured during these experiments. With exposure of the mucosa to bile, hydrogen ion back-diffusion from and sodium gain by the pouch were significantly increased and the potential difference fell. However, when the pouches were first treated with either lauroyl glycyrrhetinic acid or carbenoxolone, the bile-induced net increase in back-diffusion of hydrogen ion was significantly decreased while the changes in the net sodium flux and in the potential difference were the same as in the untreated pouches.

4222 EFFECT OF SEVERAL DRUGS ON GASTRIC POTENTIAL DIFFERENCE IN MAN. *(E.)* Murray, H. S.; Strottman, M. P.; Cooke, A. R. (Univ. Hosp., Univ. Iowa, Iowa City). *Br. Med. J.* 1(5896):19-21, 1974.

Measurement of gastric mucosal potential difference was used to determine the effect on gastric mucosal barrier of several drugs known to provoke ulcers. Studies were carried out with 6 volunteers, with 9 rheumatoid arthritis patients being treated with long-term aspirin, and with 5 arthritis patients on long-term prednisone. Unbuffered aspirin and ethanol "broke" the barrier as shown by a rapid fall in potential difference. The effects of unbuffered aspirin were dose related, with 600 mg causing a greater fall in potential difference than 300 mg. The effects of unbuffered aspirin and ethanol given together were additive and caused the greatest fall. Sodium acetylsalicylate (buffered aspirin) did not however, alter the normal potential difference. Indomethacin, phenylbutazone, and prednisone also failed to cause any change in potential difference. The patients on long-term unbuffered aspirin or long-term prednisone had readings within the normal range and responded the same as normal subjects to acute challenge with aspirin or prednisone. The studies thus show that unbuffered aspirin and ethanol will damage the gastric mucosal barrier but that buffered aspirin, indomethacin, phenylbutazone, and prednisone do not.

4223 EXTRACTION OF CIRCULATING ENDOGENOUS GASTRIN BY THE GASTRIC FUNDUS. *(E.)* Evans, J. C. W.; Reeder, D. D.; Becker, H. D.; Thompson, J. C. (Roy. Infirm., Bristol, England). *Gut* 15(2): 112-115, 1974.

Serum gastrin was determined by radioimmunoassay in 14 dogs in samples obtained simultaneously from the arterial inflow and venous outflow of the gastric fundus. Under basal conditions, transit of the gastric fundus resulted in no change in gastrin concentrations. During antral stimulation with 0.1% acetylcholine, 9 of the 14 dogs demonstrated a significant increase in gastric acid secretion. Acid production increased from a basal value of 0.10 mEq/30 min to a maximum of 0.93 mEq/30 min. In these 9 dogs the arterial concentration of serum gastrin was significantly higher (approximately 30%) than the venous concentration. There was no significant arteriovenous difference in gastrin concentration in the 5 dogs exhibiting no gastric secretory response to antral stimulation. It is concluded that the gastric fundus is an important site for the inactivation of stimulated levels of circulating gastrin.

4224 THE EFFECT OF CORTICOTROPHINE AND CORTISONE ON ARYLSULPHATASE ACTIVITY IN STOMACH MUCOSA OF RATS. *(E.)* Kozlowska, K. (Med. Sch., Gdansk, Poland). *Endokrinologie* 62(3):359-362, 1973.

Changes in the activity of the stomach mucosa arylsulfatases were studied in male Wistar rats treated with cortisone or ACTH (five 25 mg doses injected i.p. every 2 hours). Both hormones increased the arylsulfatase activity in the fundic and pyloric regions of the stomach, the increase seen with ACTH being more marked. With neither hormone was the increase statistically significant. The data showed no correlation between the lysosomal arylsulfatase activity in the stomach mucosa and the increase in sulfated polysaccharides seen after the application of ACTH and cortisone. The increase in sulfated polysaccharides could be an expression of their intensified synthesis rather than a decrease in their catabolism.

4225 INHIBITION OF ACID SECRETION IN DOG BY METIAMIDE, A HISTAMINE ANTAGONIST ACTING ON H_2 RECEPTORS. *(E.)* Grossman, M. I.; Konturek, S. J. (VA Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Gastroenterology* 66(4):517-521, 1974.

Histamine, pentagastrin, or 2-deoxyglucose were given by continuous i.v. infusion to two dogs with Heidenhain pouches and gastric fistulas. Metiamide (2.9 mg/kg) or atropine sulfate (0.1 mg/kg) were given by rapid i.v. injection 90 min after commencement of the stimulant infusions. Metiamide, but not atropine, inhibited histamine-stimulated acid secretion from both the gastric fistula and the Heidenhain pouch. Both metiamide and atropine inhibited pentagastrin-stimulated acid secretion from the main stomach and the Heidenhain pouch. The inhibition produced by atropine was more pronounced and lasted longer. Similarly, both metiamide and atropine inhibited 2-deoxyglucose-stimulated acid secretion from the main stomach (this stimulant had little effect on acid secretion from the Heidenhain pouch), with atropine producing a greater and more lasting response. The increase in acid secretion induced by liver extract infusion was as great as that induced by pentagastrin in the main stomach and twice as great as that induced by pentagastrin in the Heidenhain pouch. Both metiamide and atropine inhibited liver extract-stimulated acid secretion in the main stomach and the Heidenhain pouch, the inhibition by atropine being greater and longer lasting. The data suggest an interaction between the parietal cell receptors for histamine, gastrin, and acetylcholine.

4226 INHIBITORY EFFECT OF BROMAZEPAM ON BASAL AND BETAZOLE-STIMULATED GASTRIC ACID SECRETION IN MAN. *(E.)* Stacher, G.; Starker, D. (1st Surg. Clin., Univ. Vienna, Austria). *Gut* 15(2):116-120, 1974.

Basal as well as betazole-stimulated (1.7 mg/kg s.c.) gastric acid secretion in 6 healthy subjects (4 women and 2 men with an average age of 22.9 yr) was reduced after administration of bromazepam (0.1 mg/kg i.v.). In subjects staying awake the reduction was limited to the first two 15-min periods after injection. The reduction was highly significant in subjects who fell asleep after receiving the drug, with the low level of secretory output maintained as long as sleep lasted. After wakening there was a sharp and highly significant rise. Acid secretion in subjects who fell asleep after the simultaneous administration of betazole and bromazepam was significantly higher than after the administration of bromazepam alone. Acid secretion during natural sleep did not differ during that during bromazepam-induced sleep. Sleep by itself is apparently a more potent inhibitor of gastric secretion than bromazepam alone.

4227 ACTION OF BURIMAMIDE, A HISTAMINE ANTAGONIST, ON ACID SECRETION IN VITRO.

(E.) Shoemaker, R. L.; Buckner, E.; Spenney, J. G.; Sachs, G. (Dept. Physiol., Med., Univ. Alabama, Birmingham). *Am. J. Physiol.* 226(4):898-902, 1974.

Burimamide (5-butylmethylthiourea, 10^{-3}M) completely inhibited spontaneous acid secretion in *Rana pipiens* gastric mucosa *in vitro*. Burimamide also inhibited acid secretion stimulated by histamine (10^{-3} M), mecholyl (10^{-5} M), or pentagastrin (10^{-5} M). Aminophylline (10^{-2} M) prevented this inhibition, and only histamine (in a 1/100 M ratio to burimamide) and dibutyryl cyclic AMP (10^{-3} M) reversed inhibition induced by burimamide. These data support a sequential model for acid secretion involving an adenyl cyclase as a critical step.

4228 CALCITONIN INHIBITION OF GASTRIN SECRETION IN MAN.

(E.) Oyama, T.; Shiraki, M.; Ito, H.; Tanaka, K.; Orimo, H. (Tokyo Metropolitan Geriatric Hosp., Japan). *Endocrinol. Jap.* 20(6): 625-627, 1973.

Porcine calcitonin (4 and 40 MRC U, i.v.) caused a marked fall in serum immunoreactive gastrin in 9 patients (aged 60-72 yr) with chronic nonendocrine disorders. The fall was dose-related and was significantly greater following 40 MRC U than after 4 MRC U. A significant fall in serum immunoreactive gastrin also occurred in 5 patients (aged 65-86 yr) given i.m. injections of 40 MRC U porcine calcitonin. There were no significant changes in serum calcium in either group. These results, together with previous findings of decreased serum gastrin in patients with medullary carcinoma of the thyroid, are evidence for a suppressive effect of calcitonin on gastrin secretion.

4229 STIMULATION OF ACID AND PEPSIN SECRETION IN THE FISTULA DOG BY 4(5)-METHYL HISTAMINE, A SPECIFIC H-2 AGONIST.

(E.) Hirschowitz, B. I.; Gibson, R.; Hitchinson, G. (Univ. Alabama Med. Ctr., Birmingham). *Am. J. Dig. Dis.* 19(4): 307-314, 1974.

Gastric acid and pepsin responses to graded doses of 4-methyl histamine (5-200 μg/kg/hr i.v.) were studied in 3 gastric fistula dogs with intact vagal innervation. 4-Methyl histamine, a specific agonist for the H-2 receptor of the gastric parietal cell, stimulated about 3 times more pepsin than did histamine. With regard to H^+ response, there were no unique differences between the 2 drugs other than metabolic half-life. The lag time between start of stimulus infusion and onset of secretion was comparable (10-20 min) as were the time taken to reach peak response (45-90 min), peak output (10 mEq/15 min), rate of fade (30% in 2 hr), dose giving near-maximum response (100 μg/kg/hr), and kinetic parameters V_{max} (45 mEq/hr) and K_m (11.8 μg/kg/hr for 4-methyl histamine and 12.4 μg/kg/hr for histamine). After infusion of 4-methyl histamine was stopped, H^+ secretion declined exponentially with time, and the half-time of this slope was linearly proportional to dose. At all doses, the decay of response was several times slower than with histamine, representing the only difference between the 2 drugs as regards gastric acid secretion in the dog.

4230 EFFECT OF CALCITONIN ON MEAL-STIMULATED GASTRIC ACID SECRETION AND SERUM GASTRIN CONCENTRATION.

(E.) Bieberdorf, F. A.; Gray, T. K.; Walsh, J. H.; Fordtran, J. S. (Univ. Texas Southwestern Med. Sch., Dallas). *Gastroenterology* 66 (3):343-346, 1974.

Gastric acid secretion and serum gastrin and calcium concentrations were measured in 5 normal subjects (23 to 45 yr old) during the first 2 hr after ingestion of a normal meal. Each subject was studied three times, once after an i.v. saline infusion, and twice after the infusion of synthetic salmon calcitonin (SCT, 0.25 and 1.0 Medical Research Council U/kg/hr). During infusion with the smaller dose of SCT, the gastric acid secretory rates were slightly depressed, while after the larger dose they were markedly depressed. SCT suppressed acid secretion to the same extent during the first and second hours after eating. Neither dose of SCT had a detectable effect on the total serum calcium concentration. The postprandial serum gastrin concentrations were similar during saline and SCT infusions. Two of the subjects had diarrhea for the first few hours after the larger dose of SCT; no side effects were noted after the smaller dose of SCT or saline. The data indicate that SCT suppresses meal-stimulated acid secretion by a mechanism other than inhibition of the serum immunoreactive gastrin response.

4231 ULTRASTRUCTURE OF ARGENTOPHILS CELLS OF THE GASTRIC FUNDUS GLANDS UNDER THE INFLUENCE OF PHARMACOLOGIC STIMULATING AND INHIBITING AGENTS.

(E.) Sokolowska-Halliop, J. (Med. Acad., Lublin, Poland). *Folia Morphol. (Warsz.)* 32(4): 469-479, 1973.

The argentophil cells of the stomach were studied in 36 male guinea pigs divided into a control group and 8 experimental groups. In 4 groups, the animals were injected s.c. with atropine sulfate (1 mg/kg) and in 4 groups with pilocarpine hydrochloride (10 mg/

kg). Paralysis of parasympathetic nerve endings with atropine caused structural changes in the mitochondria, smooth and rough endoplasmic reticula, and nucleoplasm, indicating depression of secretory function. Stimulation of parasympathetic nerve endings with pilocarpine first enhanced and then depressed metabolic processes, as reflected by cytoplasmatic structural changes.

4232 EFFECT OF METIAMIDE, A HISTAMINE H_2-RECEPTOR ANTAGONIST, ON MUCOSAL BLOOD FLOW AND SERUM GASTRIN LEVELS. *(E.)* Konturek, S. J.; Tasler, J.; Obtulowicz, W.; Rehfeld, J. F. (Med. Acad., Krakow, Poland). *Gastroenterology* 66(5): 982-986, 1974.

In dogs with gastric fistulae and vagally denervated Heidenhain pouches, metiamide, a histamine H_2-receptor antagonist, (12 μmol/kg/hr i.v.) inhibited near maximal acid responses to histamine, pentagastrin, bethanechol, or a peptone meal. Atropine sulfate (0.12 μmol/kg/hr i.v.) did not significantly affect acid output induced by histamine, but was a more effective inhibitor of acid secretion stimulated by pentagastrin, bethanechol, or a peptone meal. Serum gastrin response to a peptone meal was unchanged by metiamide but partly suppressed by atropine. The inhibitory effect of metiamide was always associated with a marked reduction in mucosal blood flow. The ratio of the aminopyrine concentration in gastric juice to that in plasma was not significantly changed by metiamide, indicating that the persistent reduction in gastric mucosal blood flow was secondary to an inhibition of gastric secretion.

4233 PSYCHIC CONTROL OF GASTRIC ACID: RESPONSE TO ANTICIPATED FEEDING AND BIOFEEDBACK TRAINING IN A MAN. *(E.)* Moore, J. G.; Schenkenberg, T. (VA Hosp., Salt Lake City, Utah). *Gastroenterology* 66(5):954-959, 1974.

The psychic influence of appetizing meals on gastric acid secretion was assessed in a healthy 25-yr-old male. A significant increase in acid secretion occurred after he was exposed to appetizing meals in a banquet setting. The anticipation of an appetizing meal, with or without the banquet proceeding, appeared to be the most important underlying factor in stimulating acid secretion. He was able to significantly reduce acid secretion in anticipation of a meal only when he was threatened with denial of the meal. He was unable to increase acid secretion on command above the already elevated secretory rates observed when he was anticipating a meal reward. Attempts at self-control of acid secretion in the absence of food cues and with the aid of biofeedback techniques revealed that he was able on command to increase or decrease acid secretion.

4234 EFFECT OF PROSTAGLANDIN-E_2 ON GASTRIC SECRETION AND ON GASTRIC CIRCULATION OF TOTALLY ISOLATED EX VIVO CANINE STOMACH. *(E.)* Kowalewski, K.; Kolodej, A. (Univ. Alberta, Edmonton, Canada). *Pharmacology* 11(2):85-94, 1974.

Totally isolated canine stomachs, perfused with homologous blood, were used to study the effect of prostaglandin E_2 on gastric secretion and circulation. *Ex vivo* stomachs were stimulated by a constant infusion of histamine (150 μg/hr) into the gastric artery. When histamine-induced secretion was stabilized, prostaglandin E_2 was introduced intra-arterially for 1 hr in doses of 500, 250, and 125 μg/hr. After 1 hr, prostaglandin E_2 infusion was interrupted, but histamine stimulation continued. Prostaglandin E_2 significantly inhibited the output of gastric juice, HCl, and pepsin and reduced the concentration of HCl. The effect of prostaglandin E_2 on gastric secretion persisted and became even more pronounced after it was discontinued. Prostaglandin E_2 had a potent vasodilator effect on gastric circulation: it reduced gastric peripheral resistance and the gastric arterial perfusion pressure. This hemodynamic effect of prostaglandin E_2 disappeared after prostaglandin E_2 infusion was discontinued.

4235 GASTRIN DELIVERY TO THE GASTRIC MUCOSA AND GASTRIC ACID SECRETION. *(E.)* Blair, E. L.; Grund, E. R.; Reed, J. D.; Shaw, B. (Dept. Physiol., Univ. Newcastle upon Tyne, England). *Acta Hepatogastroenterol.* 21:80-81, 1974.

4239 THE EFFECT OF PROSTAGLANDIN E$_1$ ON EXOCRINE PANCREATIC SECRETION (IN VIVO AND IN VITRO. *(E.)* Gabryelewicz, A.; Szalaj, W.; Kinalska, I.; Stasiewicz, J.; Langiewicz, J. (Med. Acad., Bialystok, Poland). *Pol. J. Pharmacol. Pharm.* 26 (1/2):263-267, 1974.

An increase of enzyme secretion into medium and cell respiration was observed during incubation of guinea-pig pancreatic slices in Krebs phosphate buffer with cholecystokinin-pancreozymin and prostaglandin E$_1$ (PGE$_1$). PGE$_1$ induced an increase in pancreatic enzymes output in the rat *in vivo* and in the guinea-pig *in vitro*, but this effect was statistically significant only for amylase in the *in vivo* experiments. However, PGE$_1$ markedly augmented the secretion of pancreatic enzymes stimulated by cholecystokinin-pancreozymin in anesthetized rats. *In vitro*, PGE$_1$ did not affect release of enzymes stimulated by cholecystokinin-pancreozymin. The increased discharge of pancreatic enzymes into rat duodenum after administration of PGE$_1$ can be associated with its relaxing effect on muscles within the pancreaticobiliary tract. It is concluded that the effect of PGE$_1$ on exocrine pancreatic secretion investigated *in vivo* is probably affected by changes induced in pancreatic blood flow.

4240 EFFECT OF VAGOTOMY ON HORMONES STIMULATING PANCREATIC SECRETION. *(E.)* Konturek, S. J.; Becker, H. D.; Thompson, J. C. (Univ. Texas Med. Branch, Galveston). *Arch. Surg.* 108(5):704-708, 1974.

The effect of truncal vagotomy on the intestinal release of secretin, cholecystokinin, and gastrin, and on their action on pancreatic secretion, was studied in conscious mongrel dogs with chronic gastric and pancreatic fistulas. Vagotomy caused a substantial reduction of pancreatic exocrine secretion in response to the intraduodenal instillation of hydrochloric acid, amino acids, and oleic acid soap, but did not affect pancreatic secretion induced by exogenous secretin or cholecystokinin. This suggests that vagal innervation plays a permissive role in the release of these hormones from the intestinal mucosa but does not interact with them at the level of the pancreatic secretory cells. Vagotomy resulted in a substantial increase in the basal serum gastrin level, but it impaired gastrin release caused by intestinal stimulants, which indicates that the release of intestinal gastrin may also be under cholinergic control.

4241 EARLY DISSOCIATION OF PROTEIN SYNTHESIS AND AMYLASE SECRETION FOLLOWING HORMONAL STIMULATION OF THE PANCREAS. *(E.)* Mongeau, R.; Couture, Y.; Dunnigan, J.; Morisset, J. (Sherbrooke Univ., Quebec, Canada). *Can. J. Physiol. Pharmacol.* 52(2):198-205, 1974.

The secretion of the various pancreatic enzymes can be increased by hormonal and cholinergic stimulation. Synthesis of the enzymes may be modified or remain constant according to different metabolic conditions. The secretion and synthesis of the pancreatic proteins were studied in parallel to determine if secretion triggers synthesis or if both phenomena are controlled by separate mechanisms. The stimulants were injected *in vivo* and the pancreatic secretions were collected for different periods of time. The animals were then sacrificed and protein synthesis was measured *in vitro* along with the amylase secreted into the incubation medium. The results show that protein synthesis is decreased during the first 15 minutes after a single injection or infusion of both cholecystokinin-pancreozymin and secretin. This reduction was associated with an increase in amylase secreted into the incubation medium. However, at 30 minutes after the hormonal stimulation, protein synthesis is increased while secretion into the incubation medium had returned to control levels. This increase in protein synthesis lasts for at least 1 hour. These results strongly suggest that pancreatic enzyme secretion and synthesis are dissociated in the early minutes following hormonal stimulation.

4242 BIOCHEMICAL REACTIONS INVOLVED IN PANCREATIC ENZYME SECRETION. I. ACTIVATION OF THE ADENYLATE CYCLASE COMPLEX. *(E.)* Beaudoin, A. R.; Marois, C.; Dunnigan, J.; Morisset, J. (Sherbrooke Univ., Quebec, Canada). *Can. J. Physiol. Pharmacol.* 52(2):174-182, 1974.

Pancreatic amylase secretion was studied using an *in vitro* system. Secretion was increased by urecholine and cholecystokinin-pancreozymin. Addition of tetracaine and dibucaine to the medium abolished secretion stimulated by urecholine and decreased by 75% that stimulated by cholecystokinin-pancreozymin. In contrast, an increase in enzyme secretion was observed after dibutyryl cyclic AMP; this was potentiated by tetracaine added to the medium. Oxygen uptake by pieces of pancreatic tissue was not affected by tetracaine. Adenylate cyclase activity, increased *in vitro* when cholecystokinin-pancreozymin was added to a pancreas homogenate, was inhibited by 15% by tetracaine at 2 mM and by 67.5% at the 10 mM concentration. From known data of biochemical reactions associated with the process of secretion and the results described, a model is indicated for the activation of the pancreatic adenylate cyclase complex. Associated with the depolarization of the acinar cell plasma membrane by urecholine and cholecystokinin-pancreozymin and an inward movement of sodium and calcium, there is an immediate rise in adenylate cyclase activity within 10 seconds which is timed with the initiation of amylase secretion.

4243 INHIBITORY EFFECT OF GLUCAGON ON HUMAN PANCREATIC SECRETION. *(Ger.)* Steffen, C.; Goebell, H.; Baltzer, G.; Durr, H. K. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1423-1425, 1972.

Pancreatic secretion was investigated in 19 normal fasting volunteers (11 men and 8 women with an average age of 40 yr) for 1 hr after stimulation with secretin or secretin-pancreozymin (1 clinical U/kg/hr) nd for another hr after infusion of glucagon (1 or mg/75 kg/hr). Glucagon was infused for 1 hr at he beginning of the test in 5 subjects. Although lucagon had little effect on the volume of pancreatic uice secreted or on bicarbonate secretion, trypsin, hymotrypsin, and lipase secretion was inhibited by 0-60%, depending upon the dose of glucagon employed. hen 5 mg/75 kg/hr glucagon was infused together ith secretin and pancreozymin, enzyme secretion was low from the start and only increased 15 min after iscontinuation of glucagon infusion. No change ccurred in serum calcium levels during glucagon in- usion, but blood sugar concentrations increased sig- ificantly. These findings suggested that glucagon oes not act directly on pancreatic enzyme secretion, ut might act by liberating calcitonin. However, his hypothesis was disproved by experiments per- ormed on anesthetized dogs which demonstrated that otal thyroidectomy did not eliminate the inhibitory ffect of glucagon on pancreatic enzyme secretion. nother possibility is that glucagon causes changes n cell permeability for calcium, resulting in an ntracellular calcium deficiency which inhibits en- yme secretion.

4244 SECRETION OF DIGESTIVE ENZYME DERIVED FROM TWO PARALLEL INTRACELLULAR POOLS. *(E.)* Rothman, S. S.; Isenman, L. D. (Dept. Physiol., Univ. California, San Francisco). *Am. J. Physiol.* 226(5):1082-1087, 1974.

Both methacholine chloride (1.0 mg/100 ml) and cholecystokinin-pancreozymin (6.25 Ivy dog U/100 ml) greatly decreased the specific radioactivity of digestive enzymes secreted by the rabbit pancreas *in vitro* when these stimulants were added to the bathing medium 2 hr after ^{14}C-L-leucine had been introduced. Inhibition was approximately 97% for methacholine chloride and 78% for cholecystokinin-pancreozymin. This observation indicates that secreted proteins are derived from 2 parallel intracellular pools, slowly and rapidly equilibrating, and probably consist of zymogen granules and cytoplasm, resp. The secretory stimulants preferentially increased protein secretion from the slow pool. In the unstimulated state secretion from the rapid pool accounted for no less than 18 to 71% of the total protein secreted for individual experiments. A 5-min delay in the response to methacholine chloride was observed. During this delay, secretion from the rapid pool was inhibited relative to secretion from the slow pool, even though overall protein output was unchanged. This suggests that competitive inhibition occurred between secretory proteins derived from the 2 different pools and, at least with cholinergic stimuli, enzymes derived from these 2 pools mix prior to their transport out of the secretory cell.

4245 ACCUMULATION OF AMYLASE BY CHICK PANCREAS IN ORGAN CULTURE: EFFECT OF HYDROCORTISONE. *(E.)* Yalovsky, U.; Heller, H.; Kulka, R. G. (Dept. Biol. Chem. Hebrew Univ., Jerusalem, Israel). *Exp. Cell Res.* 80(2):322-328, 1973.

Accumulation of amylase by pancreas explants from 7-14-day-old chick embryos was studied in organ culture. The explants produced amylase but there was no increase in their total DNA and little if any increase in their total protein. Most of the amylase in the cultures was released into the culture medium. The younger the age at which the pancreas was taken, the greater the relative increase of amylase activity in the culture. After several days of culture, accumulation of amylase slowed or stopped. Hydrocortisone markedly increased the amount of amylase produced by the explants. The hormone had little or no effect on the initial rate of amylase production by the explants. However, addition of hydrocortisone to the culture resulted in a continuing increase of amylase activity when synthesis of the enzyme had ceased in the controls without added hormone. These observations support the hypothesis that corticosteroids are implicated in the later stages of differentiation of the embryonic chick pancreas.

4246 CANINE PANCREATIC RESPONSES TO INTESTINALLY PERFUSED FAT AND PRODUCTS OF FAT DIGESTION. *(E.)* Meyer, J. H.; Jones, R. S. (VA Hosp., San Francisco, Calif.). *Am. J. Physiol.* 226(5):1178-1187, 1974.

In dogs with chronic gastric and pancreatic fistulas, pancreatic outputs were measured in response to intestinally perfused fatty acid soaps, fatty acids dispersed in α-monolein + bile, or triglyceride (corn oil) with or without added active pancreatic juice. All perfusates were at pH 7 or higher and were approximately isotonic to blood. Fatty acids of less than 9 carbons in chain length had no effect on pancreatic secretion while fatty acids longer than 9 carbons stimulated pancreatic secretion in a dose-dependent fashion over concentrations ranging from 5 to 160 mM. Juice stimulated by fatty acids had a higher bicarbonate:protein ratio than could be accounted for solely by the release of endogenous cholecystokinin. Monolein stimulated a juice high in protein but low in bicarbonate. Unlike fatty acid stimulation, stimulation by monolein produced a juice with bicarbonate: protein ratios similar to those obtained by stimulation with cholecystokinin or the octapeptide of cholecystokinin. Large amounts of luminal triglyceride did not stimulate unless the corn oil was converted into products, presumably free fatty acids and monoglycerides, which were capable of stimulating pancreatic secretion.

4247 RELATIVE POTENCIES OF MAGNESIUM (Mg^{++}), CALCIUM (Ca^{++}) AND OLEIC ACID (C_{18}) ON PANCREATIC, GALLBLADDER AND INTESTINAL FUNCTION IN MAN. *(E.)* Malagelada, J. R.; Holtermuller, K. H.; Go, V. L. W. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 66(4):737, 1974.

SECRETION AND METABOLISM

Hepatobiliary Tract

4255 STORAGE IRON KINETICS. IV. CELLULAR DISTRIBUTION OF FERRITIN IRON STORES IN RAT LIVER. *(E.)* Cook, J. D.; Hershko, C.; Finch, C. A. (Univ. Washington Sch. Med., Seattle). *Proc. Soc. Exp. Biol. Med.* 145(4):1378-1381, 1974.

A study was undertaken in female Wistar rats to determine the distribution of ferritin iron stores between reticuloendothelial and parenchymal cells of the liver. After selective radioiron labeling of the reticuloendothelial cell ferritin compartment with heat-damaged erythrocytes, the ratio of specific activities of ferritin extracted from whole liver and from isolated Kupffer cells provided a measure of the size of ferritin iron stores within each cellular compartment. These studies suggested that a mean of 14.3% of hepatic ferritin was contained in RE cells. While this figure may be taken as a maximal estimate of RE ferritin, it does not exclude the possibility of significant contamination of the Kupffer cell fraction by parenchymal ferritin. RE cell concentrates obtained with pronase were in fact significantly contaminated. When corrected for this cross-contamination by parenchymal cell ferritin, the RE cell ferritin was calculated to be only 2.6% of the total-liver ferritin, indicating that, in the rat, hepatic ferritin can be equated with parenchymal ferritin stores.

4256 PELIOSIS-LIKE CHANGES INDUCED BY PHALLOIDIN IN THE RAT LIVER. A LIGHT AND ELECTRON MICROSCOPIC STUDY. *(E.)* Tuchweber, B.; Kovacs, K.; Khandekar, J. D.; Garg, B. D. (Inst. Surg. Exp. Med., Univ. of Montreal, Canada). *J. Med. (Basel)* 4(6):327-345, 1973.

Administration of phalloidin (0.3 mg/100 mg i.p.) to ARS/Sprague-Dawley rats produced lesions resembling peliosis hepatitis in man and animals. Under the electron microscope, the first change observed in the hepatocytes is the formation of cytoplasmic vacuoles resulting from invagination of the cytoplasmic membranes. At the same time, microvilli along Disse's spaces virtually disappear. Later, the cytoplasmic membranes display focal interruptions, and RBC are seen in the greatly dilated sinusoids and in the cytoplasmic vacuoles. The pathogenesis of phalloidin-induced liver lesions is not clear. Early hepatic changes resemble those seen after ischemia; hence, microcirculatory disturbances may play a role in the production of this liver injury.

4257 AUGMENTATION OF THE CLEARANCE OF SULFOBROMOPHTHALEIN BY PHENOTHIAZINES. *(Fr.)* Denis, Ph.; Le Leannec, A.-M.; Benhamou, J.-P. (Beaujon Hosp., Clichy, France). *Nouv. Presse Med.* 2(43):2881-2883, 1973.

The BSP clearance was investigated in 30 psychiatric patients who had been taking large doses of phenothiazines (thioridazine, methotrimeprazine, fluphenazine, pericyazine) for 2 months or more to determine whether phenothiazines increase BSP clearance in man as they do in the rat. Controls consisted of 11 psychiatric patients receiving no medication. The first-order rate constant (K_1) for plasma decay of BSP was measured 4 and 16 min after i.v. injection of the dye. K_1 was significantly higher (mean of 0.175 ± 0.042/min) in treated than in untreated patients (mean of 0.130 ± 0.016/min). In 13 of the 30

eated patients, K$_1$ was above the upper limit of
e normal range. Elevated K$_1$ values in patients
king phenothiazine derivatives are probably due to
creases in hepatic extraction of the dye.

58 PRODUCTION OF SERUM PROTEINS BY PRIMARY
CULTURES OF ADULT HUMAN LIVER. *(E.)* Le
illy, Y.; Launois, B.; Lenoir, P.; Bourel, M.
ontchaillou Hosp., Rennes, Fr.). *Biomedicine*
(3):248-255, 1973.

corporation of ^{14}C(U)-L-isoleucine and ^{14}C(U)-L-
sine into orosomucoid, α_1-antitrypsin, ceruloplas-
n, fibrinogen, transferrin, hemopexin, albumin,
-lipoprotein, α_2-macroglobulin, and haptoglobin
s investigated in 15 primary cultures from explants
human adult liver. Radioimmunoelectrophoresis
evealed that these 10 plasma proteins were present
all 15 of the primary liver cultures but were
ever present simultaneously in the medium of a
ingle primary culture. The findings suggest that
rosomucoid, α_1-antitrypsin, ceruloplasmin, and fibri-
ogen are products of epithelial cells (types III
d IV), while transferrin and hemopexin are synthe-
ized by type V cells which are morphologically in-
ermediate between fibroblasts (type I) and epithe-
ial cells (type IV). The 4 remaining proteins were
ound in all cultures independent of their dominant
ell type.

259 TRIGLYCERIDE LEVELS AND OXYGEN CONSUMPTION
OF LIVER, KIDNEY AND HEART FOLLOWING A HIGH
AT CHOLINE FREE DIET IN RATS. *(E.)* Agostini, C.;
ngelotti, A. (Inst. Gen. Pathol., Univ. Milan, I-
aly). *Pathol. Eur.* 8(2):105-111, 1973.

he triglyceride contents of liver, kidney, and
eart were measured in female Wistar rats fed for 3,
and 12 days on choline-free diet containing 31%
otal lipids, 15% total protein, and 48% total car-
ohydrates. Controls were fed a diet containing
5% total protein, 5% total lipids, and 59% total
arbohydrate. The effect of refeeding the rats on a
ormal diet for 6 days was also observed. The oxy-
en consumption by slices of the same organs in the
resence and in the absence of butyrate was investi-
ated. Triglyceride levels progressively increased
n liver and kidney during feeding with the high-fat,
holine-free diet. Refeeding the rats a normal diet
trongly reduced the accumulation of triglycerides
n these organs. Triglyceride levels were higher
n hearts of rats fed the high fat, choline free
iet for 3 days, but no further increase occurred
hen the period on this diet was lengthened. Re-
feeding the rats a normal diet did not modify lipid
accumulation. The presence of butyrate did not modify the oxygen consumption of liver and kidney slices of normal rats. Oxygen consumption was not statistically modified by feeding the rats the high-fat, choline-free diet, but on the 12th day, these organs showed a significant increase in the oxygen uptake in the presence of butyrate. Butyrate also increased the oxygen uptake by heart slices of normal rats. The hearts of those on the 12-day diet showed an increase in oxygen uptake which was not further stimulated by the presence of butyrate.

4260 EFFECT OF DIETARY METHIONINE AND CHOLESTEROL ON LIPID METABOLISM OF RATS. *(E.)* Miller, J. (Univ. Georgia Coll. Agr. Exp. Stations, Georgia Station). *Nutr. Rep. International* 9(2): 125-134, 1974.

Addition of 1% cholesterol to diets containing 14.3% casein and 5% Wesson oil caused hepatomegaly, due primarily to increased deposition of neutral lipids, especially cholesterol esters and triglycerides, in the livers of weanling male Sprague-Dawley rats. Increases which occurred in free fatty acids were caused by major increases in oleic, linoleic, palmitic, and palmitoleic acids. While the first 3 of these acids together constituted about 90% of the dietary fatty acids and the diet contained only 0.3% of palmitoleic acid, this acid accounted for more than 18% of the increase in total fatty acids in the livers of rats fed diets containing cholesterol. A concomitant reduction occurred in the fatty acid content of adipose tissue and the aorta. Dietary supplementation with 1% methionine decreased the deposition of cholesterol in livers of animals fed the high-cholesterol diets. It is postulated that accumulation of cholesterol in the liver interfered with hepatic lipid metabolism and transfer of lipids to extra-hepatic tissues.

4261 CANALICULAR BILE FLOW AND BROMOSULFOPHTHALEIN TRANSPORT MAXIMUM: THE EFFECT OF A BILE SALT-INDEPENDENT CHOLERETIC, SC-2644. *(E.)* Gibson, G. E.; Forker, E. L. (Dept. Physiol., Univ. Iowa, Iowa City). *Gastroenterology* 66(5):1046-1053, 1974.

Cannulae were placed in the common bile duct, a femoral vein, and the contralateral femoral artery of female mongrel dogs. The secretory response to infusions of taurocholate (1.5, 2.0, or 3.0 μmoles/min/kg), β-(2,4-diamethoxy-5-cyclohexylbenzoyl)-propionic acid (0.5 μmoles/min/kg), of dehydrocholate (1.9 μmoles/min/kg) was determined. Both taurocholate and β-(2,4-diamethoxy-5-cyclohexylgenzoyl)-propionic acid produced increases in bile flow and equivalent increases in the biliary clearance of erythritol. Only taurocholate increased BSP transport maximum and increased the fraction of unconjugated dye appearing in bile. It was therefore concluded that the taurocholate-dependent changes in BSP excretion were not attributable to the associated choleresis, but instead represented a specific effect of the bile acid. It could not be determined whether an effect of taurocholate on the membrane transport of BSP or micellar sequestration of dye in the canalicular lumen was the more important mechanism. However, indirect evidence does suggest that alterations in the intracellular conjugation of BSP does not account for the bile acid-dependent changes in BSP transport maximum.

4262 REGULATION OF BILE FORMATION IN RABBITS AND GUINEA PIGS. *(E.)* Shaw, H. M.; Heath, T. J. (Sch. Physiol. Pharmacol., Univ. New South Wales, Kensington, Australia). *Q. J. Exp. Physiol.* 59(2):93-102, 1974.

Saline infusion to compensate for bile loss of water and electrolytes due to interrupted enterohepatic circulation of bile salts, enabled bile flow in conscious rabbits and guinea pigs to remain constant for several hours. This indicates that bile flow in these species is not as highly dependent on bile salt secretion as it is in dogs and man. Secretin (0.3, 3.0, 30 and 300 mu/min/kg), cholecystokinin-pancreozymin (0.036, 0.36, 0.9, 1.8, and 3.6 u/min/kg) and pentagastrin (0.45, 0.9, 4.5, and 9.0 ug/min/kg) were ineffective as choleretics in rabbits although the doses of these exogeneously-administered hormones were sufficient to significantly increase either pancreatic or gastric secretion. After the administration of secretin and cholecystokinin-pancreozymin to guinea pigs, trivial choleretic responses were noted. Attempts to elicit a choleresis by release of endogenous hormones again caused no changes in bile formation although pancreatic secretion was stimulated in rabbits. Peptone infusion was not effective in stimulating the release of endogenous cholecystokinin-pancreozymin. These results suggest that factors influencing bile formation in rabbits and guinea pigs differ from those in other species. This difference is related to the eating habits of the different species. In carnivores, food is taken intermittently, and thus delivery of bile to the duodenum is intermittent and peaks in bile output are induced by the release of gastrointestinal hormones. In herbivores, however, food probably enters the intestine more or less continuously, bile is formed at a constant high rate and these hormones are less likely to have an essential role in bile formation.

4263 TURNOVER OF HEPATIC CYTOCHROME P-450 IN EXPERIMENTAL CHOLESTASIS. *(E.)*

Denk, H.; Greim, H.; Hutterer, F.; Schanffner, F.; Popper, H. (Mt. Sinai Sch. Med., New York, N.Y.). *Exp. Mol. Pathol.* 19(2):241-247, 1973.

Hypertrophy of smooth microsomal membranes was observed in mole Sprague-Dawley rats after bile duct ligation. In contrast to typical induction, the membranes were deficient in cytochrome P-450. The total cytochrome P-450 content of the liver homogenate, however, remained unchanged. To clarify the mechanism of the developement of cytochrome P-450-deficient membranes in cholestasis, the half life of the heme portion of cytochrome P-450 and the initial rate of synthesis of cytochrome P-450 and b_5 hemes were compared in bile duct ligated rats and in control animals after labeling the heme by injection of the precursor, δ-(4-^{14}C)aminolevulinic acid. The half lives were not significantly different, which eliminates the possibility that selective destruction of cytochrome P-450 had occurred. Depression of cytochromal heme synthesis was not observed. The relative cytochrome P-450 deficiency during mechanical cholestasis is probably caused by proliferation of components of the endoplasmic reticulum other than the hemoprotein.

4264 BILIRUBIN AND BILIVERDIN EXCRETION BY THE CHICKEN. *(E.)*

Lin, G. L.; Himes, J. A.; Cornelius, C. E. (Coll. Vet. Med., Univ. Florida, Gainesville). *Am. J. Physiol.* 226(4): 881-885, 1974.

The mean endogenous bile flow measured in 29 chickens was 20.1 μl/kg/min. Endogenous biliverdin and bilirubin excretory rates were 14.7 and 0.9 μg/kg/min, resp. Excretory rates for total endogenous bile pigments were greater than in other species, with bilirubin rates accounting for only 6% of the total bile pigments. Biliverdin was more readily excreted into bile than bilirubin during i.v. infusions of mixtures. Mean excretory and biliary concentration maxima for biliverdin were 94 μg/kg/min and 888 mg/100 ml, resp. Bilirubin infusion trials revealed the transport maxima and concentration maxima for bilirubin in bile were much lower in the chicken than in other species, 10.2 μg/kg/min and 72 mg/100 ml, resp. The limited capacity of the avian liver to excrete bilirubin may relate in part to the existence of very low levels of bilirubin glucuronyl transferase activity in the avian liver. Infusions of unconjugated bilirubin had no effect on endogenous biliverdin excretion, suggesting that the presence of biliverdin in chicken bile is most likely not due to posthepatic oxidation of bilirubin. There appeared to be little if any net conversion of infused biliverdin to bilirubin. Thus the chicken represents a unique model for the study of bile pigment excretion. With little hepatic bilirubin glucuronyl transferase activity and little or no biliverdin reductase activity in the tissues, direct excretion of biliverdin into bile is the major pathway for the elimination of bile pigments.

4265 PROTECTIVE EFFECT OF ZINC ON CARBON TETTRACHLORIDE-INDUCED LIVER INJURY IN RATS. *(E.)*

Chvapil, M.; Ryan, J. N.; Elias, S. L.; Peng, Y. M. (Coll. Med., Univ. Arizona, Tucson). *Exp. Mol. Pathol.* 19(2):186-196, 1973.

In rats treated twice weekly for 20 or 34 days with CCl_4(0.2 ml/100 g, i.p.), a significant increase occurred in the content of malonaldehyde in microsomal and mitochondrial fractions of the liver. The rise in this indirect index of lipid peroxidation correlated with labilization of lysosomes, as evidenced by an increase in free β-glucuronidase present in the 15,000*g* supernatant of the liver homogenate. At the same time, the amount and the synthesis of collagen was significantly elevated. After zinc acetate administration (5 mg/100 g/day p.o. through a stomach tube) to rats receiving CCl_4, the content of malonaldehyde in the microsomal, as well as the mitochondrial fraction of the liver, was significantly lower. This correlated with a decrease in free β-glucuronidase and a decrease in the amount and in the rate of biosynthesis of collagen. Administration of zinc to normal rats had no effect on the amount and synthesis of collagen in the liver. The free and total activity of lysosomal β-glucuronidase in the liver was also unaltered by zinc in normal animals. The level of malonaldehyde was inhibited only in the microsomal fraction. In rats kept on a diet high in zinc (100 ppm), the content of endogenously-, as well as exogenously-induced

alonaldehyde in the liver was lower. It is be-
ieved that zinc protects the liver against the
oxious effect of CCl_4 primarily by interference with
ipid-peroxidation-related tissue damage.

266 D-GALACTOSAMINE HEPATOTOXICITY. III. NORMOACTIVE SMOOTH ENDOPLASMIC RETICULUM AND MODIFICATION BY PHENOBARBITAL. *(E.)*
off, R. S.; Davidson, L. J.; Gordon, G.; Sabesin, S.
. (Boston VA Hosp., Mass.). *Exp. Mol. Pathol.* 19(2):
68-177, 1973.

he administration of a single dose of D-galacto-
amine HCl (375 mg/kg i.p.) to female rats produces
evere hepatocellular necrosis. Ultrastructural
tudies disclosed a variety of nuclear and cytoplas-
ic changes including focal and diffuse hyperplasia
f the smooth endoplasmic reticulum. The functional
apacity of the hyperplastic smooth endoplasmic
eticulum was investigated by several criteria.
entobarbital sleeping time determined 6, 16, and 24
r after D-galactosamine injection was similar to
hat observed in saline-treated control animals.
epatic microsomal protein concentration, cytochrome
-450 content, and NADPH cytochrome c-reductase
ctivity measured at 20 hr were similar in D-galact-
samine-treated and control animals. Thus, using
hese modalities, the hyperplastic smooth endoplasmic
eticulum induced by D-galactosamine was not associ-
ted with an altered microsomal drug metabolizing
ctivity. When phenobarbital was administered in
daily dose of 80 mg/kg for 4 days prior to
-galactosamine, the histological evidence of
epatocellular injury and lipid accumulation was
ess severe than in animals receiving D-galactosamine
lone. The mechanisms of the modification of
epatotoxicity and fatty liver by phenobarbital
emain to be determined.

267 METABOLIC ACTIVITY AND RADIO-REACTION OF THE ISOLATED PERFUSED RAT LIVER.
Ger.) Konig, K.; Stahler, F.; Ungemach, R.
Inst. Biophysics Radiation Biol., Univ. Hamburg,
ermany). *Stralentherapie* 146(4):478-489, 1973.

he protein metabolism of the liver of rats was
timulated by deproteinization of the blood plasma
ith exchange transfusion. With isolated organ
erfusion, the reaction of the liver was tested
ithout the influences of the total organism.
y variation of the time intervals between de-
roteinization and 3-hr perfusion with ^{3}H-leucine,
aximum stimulation of albumin occurred 6-12 hr
fter deproteinization, while maximum stimulation
f globulin occurred 24 hr after deproteinization.
he highest net protein synthesis was found 24 hr
fter deproteinization. The effect of irradiation
as investigated during a 3-hr perfusion 24 hr
fter deproteinization. After irradiation with
00 r, the induction of additional synthesis of
lasma proteins was almost completely suppressed.
he lack of cellular activity disclosed damage
aused by irradiation and intensified the degree
f radio-reaction.

4268 INDUCED ALTERATIONS IN THE RATE-LIMITING ENZYMES OF HEPATIC CHOLESTEROL AND BILE ACID SYNTHESIS IN THE HAMSTER. *(E.)* Schoenfield, L. J.; Bonorris, G G.; Ganz, P. (Cedars Sinai Med. Ctr., Los Angeles, Calif.). *J. Lab. Clin. Med.* 82(6): 858-868, 1974.

The effects of bile acids and of certain potential cholelithiasis therapeutic agents, i.e. cholestyramine and phenobarbital, on the rate-limiting hepatic enzymes of cholesterol synthesis (β-hydroxyl-β-methylglutaryl coenzyme A reductase) and of bile acid synthesis (7-α-hydroxylase) were determined in hamsters. Cholic and chenodeoxycholic acids were administered intragastrically in a 16% solution of ethanol (43 mg/kg/day). Cholestyramine was added to the diet (5% by weight). Phenobarbital was given i.p. (5 mg/kg/day). The duration of treatment was 2 weeks. After sacrifice of the animals, portions of liver were taken for measurements of enzyme activity and of cholesterol and bile acid content. Administration of cholic or chenodeoxycholic acid inhibited β-hydroxyl-β-methylglutaryl coenzyme A reductase, as revealed by decreased *in vitro* cholesterol synthesis, and 7-α-hydroxylase, as revealed by decreased *in vitro* bile acid synthesis. At the same time, administration of these compounds resulted in increased concentrations of cholesterol and bile acids in the liver. Chenodeoxycholic acid inhibited cholesterol synthesis (61%) more than it inhibited bile acid synthesis (49%), whereas cholic acid inhibited bile acid synthesis (32%) more than it inhibited cholesterol synthesis (26%). In contrast, cholestyramine caused stimulation of cholesterol synthesis (253%) and an even more pronounced increase in bile acid synthesis (464%), while hepatic cholesterol and total bile acid content did not change and deoxycholic acid virtually disappeared. Phenobarbital similarly induced stimulation of cholesterol synthesis (151%) and bile acid synthesis (176%) while with this agent the hepatic concentrations of cholesterol and bile acids increased.

4269 BILIRUBIN: A POTENT INHIBITOR OF NAD^+-LINKED ISOCITRATE DEHYDROGENASE. *(E.)* Ogasawara, N.; Watanabe, T.; Goto, H. (Dept. Biochem., Inst. Develop. Res., Kasugai, Japan). *Biochim. Biophys. Acta* 327(2):233-237,1973.

Bilirubin (3.5 μM) was found to be an effective inhibitor of NAD^+-linked rat brain isocitrate dehydrogenase in Tris HCl buffer at pH 7.5. In the absence of ADP, the dehydrogenase showed a cooperative effect toward isocitrate, and the saturation curve was slightly sigmoidal whereby an apparent K_m of 5 mM was obtained. In the presence of ADP (1.33 mM), the apparent affinity of the enzyme for isocitrate increased, and the kinetics shifted to near hyperbolic and an apparent K_m of 0.7 mM. Bilirubin affected only the apparent affinity of the enzyme for isocitrate and the V was unaffected by this modifier. Thus, bilirubin inhibits the NAD^+-linked isocitrate dehydrogenase at the lower isocitrate concentrations and the inhibition is overcome with increasing concentration of isocitrate. The overall result is a shifting of the activity curve to the right with bilirubin and a corresponding increase in the sigmoidicity of the curve. Bilirubin concentrations as low as 0.35 μM produced detectable inhibition. It was suggested that bilirubin either competes for the isocitrate binding site or occupies a separate allosteric site. Neither the mitochondrial nor the cytoplasmic NADP$^+$ enzymes were significantly affected with up to 6 μM of bilirubin. Although the significance *in vivo* of the bilirubin inhibition of NAD$^+$-linked isocitrate dehydrogenase is not known, the very low concentration of bilirubin necessary to alter the activity *in vitro* suggests that the phenomenon could be significant in the pathogenesis of bilirubin encephalopathy.

4270 EFFECT OF ETHANOL ON LIVER TRIGLYCERIDE CONCENTRATION IN FED AND FASTED RATS. *(E.)* Johnson, O. (Dept. Chem., Univ. Umea, Sweden). *Lipids* 9(1):57-60, 1973.

The effect of ethanol, given p.o. through a stomach tube (6 g/kg) or by i.p. injection (3.75 g/kg), on the liver triglyceride concentration was studied in female Sprague-Dawley rats which were fasted or fed *ad libitum*. Independent of the route of administration, ethanol increased the liver triglyceride concentration in fasted rats during an 8 hr period but caused a much smaller increase in the *ad libitum* fed rats. The incorporation of i.v. injected ^{3}H-oleic acid into the liver triglycerides increased significantly after ethanol feeding in fasted but not in fed rats. Based upon this and the plasma free fatty acid concentrations, it was concluded that ethanol causes a marked increase in the utilization of plasma free fatty acids for synthesis of liver triglycerides in fasted but not in fed rats.

4271 SYNERGISM BETWEEN MERCAPTANS AND AMMONIA OR FATTY ACIDS IN THE PRODUCTION OF COMA: A POSSIBLE ROLE FOR MERCAPTANS IN THE PATHOGENESIS OF HEPATIC COMA. *(E.)* Zieve, L.; Doizaki, W. M.; Zieve, F. J. (Minneapolis Veterans Hosp., Minn.). *J. Lab. Clin. Med.* 83(1):16-28, 1974.

The coma-producing properties of methanethiol, ethanethiol, and dimethylsulfide were studied in male Holtzman or Sprague-Dawley rats. Coma occurred in 50% of the rats when the air they breathed contained 0.16% methanethiol, 3.3% ethanethiol, or 9.6% dimethylsulfide by volume. The blood concentrations at which coma occurred were 0.5 nm/ml methanethiol, 200 nm/ml ethanethiol, and 7000 nm/ml dimethylsulfide. The doses of ammonium ion or octanoate at which rats went into coma were greatly reduced when subcoma doses of mercaptans were simultaneously administered. The addition of small subcoma doses of methanethiol to subcoma doses of ammonium ion caused coma in all animals and a substantial rise in blood ammonia, suggesting that the mercaptan interferes with conversion of ammonia to urea in the liver. Conversely, the addition of small subcoma doses of ammonium ion or of fatty acid to a small subcoma dose of methanethiol caused coma in all animals and a marked rise in the blood methanethiol concentration, suggesting that the ammonium ion interferes with breakdown of methanethiol by the liver. Normal rats became comatose when blood or plasma levels of methanethiol, ammonia, and free fatty acids reached levels found in hepatic coma following acute massive necrosis of the liver. Thus it is concluded that the synergistic action of these 3 toxic substances accounts for the coma of experimental heaptic necrosis. It is suggested that methanethiol may play a role as an augmenter or intensifier of the toxic effects of ammonia and fatty acids in human hepatic failure.

4272 INCREASE IN HEPATIC NAD LEVEL ITS EFFECT ON THE REDOX STATE AND ON ETHANOL AND ACETALDEHYDE METABOLISM. *(E.)* Eriksson, C. J. P. (Res. Lab., State Alcohol Monopoly, Helsinki, Finland). *FEBS Lett.* 40(2):317-320, 1974.

A group of male Wistar rats received nicotinamide (5.0 mg/kg. i.p.) while a second group served as controls. Ethanol was given to both groups (1.18 g/kg, i.p.) 8 hr later. Ethanol decreased total hepatic nictinamide adenine dinucleotide (NAD) with a consequent rise in reduced NAD (NADH) in all rats. In rats receiving nicotinamide, a 5-fold increase in total liver NAD was noted on receipt of the ethanol, but no change occurred in NADH. These results could mean either that NAD accumulated in some form in a compartment other than the cytosol, or that the increased NAD liberated bound NADH in the cytosol. This would keep the ratio between the free nucleotides unchanged. The rate of ethanol oxidation in the liver cytosol can be modified primarily by the enzyme activity, acetaldehyde/ethanol ratio, and free NADH/free NAD ratio in this cell compartment. Increasing hepatic NAD with nicotinamide had no effect on ethanol elimination. Thus, NAD deficiency does not limit ethanol oxidation. Assuming that the cell compartment where acetaldehyde is oxidized is supplied with some of the increased NAD, then the lowered acetaldehyde level in the liver and blood of rats treated with nicotinamide suggests that NAD deficiency is one factor limiting the rate of hepatic acetaldehyde oxidation. Alternatively, instead of a difference in the rate of acetaldehyde oxidation, the lower acetaldehyde levels in the nicotinamide-treated rats could be due to the slightly decreased ethanol oxidation rate which was found in these animals.

4273 SELECTIVE BILIARY OBSTRUCTION: A MODEL FOR THE STUDY OF LIPID METABOLISM IN CHOLESTASIS. *(E.)* Cooper, A. D.; Jones, A. L.; Koldinger, R. E.; Ockner, R. K. (Univ. Calif. Med. Sch., San Francisco). *Gastroenterology* 66(4):574-585, 1974.

nodel of cholestasis has been developed in
e rat in which bile duct obstructed and un-
structed liver tissue from the same animal
n be compared. The model involves selective
struction of bile ducts draining the median
patic lobe in male Sprague-Dawley rats.
ght microscopic changes consistent with
olestasis were found in the obstructed
dian lobe, but not in the unobstructed
ght lobe. Electron microscope examination
vealed osmiophilic material in the canaliculi
the obstructed side, while on the unobstructed
de the prominent Golgi apparatus, moderately
lated canaliculi, and intact microvilli
ggest increased bile secretory activity.
ncentrations of total and free cholesterol
d of phospholipids were similar in the
ssues of unobstructed and obstructed hepatic
bes. Levels of serum cholesterol, phospholipids,
d alkaline phosphatase were significantly
evated. An abnormal lipoprotein, characteristic
biliary obstruction, also appeared. It is
ggested that these differences between complete
d selective obstruction are due at least in
rt to the presence of functioning, i.e.,
le-secreting, liver tissue in the latter
rcumstance. The morphological changes observed
total obstruction may depend on the accumulation
the hepatocyte of substances which are normally
creted, e.g., bile salts. It is felt that the
thod of selective biliary obstruction may be
ed as an experimental approach to further
ucidate the abnormalities in lipid and lipo-
otein metabolism associated with cholestasis,
d the process of bile secretion in general.

74 PRIMATE BILIARY PHYSIOLOGY. IX. EFFECTS
OF ACUTE BILIARY OBSTRUCTION ON BILIARY
PID METABOLISM IN THE MONKEY. *(E.)* Redinger,
N.; Strasberg, S. M.; Small, D. M. (Boston
iv. Sch. Med., Mass.). *Am. J. Physiol.*
6(4):776-783, 1974.

alth well-fed rhesus monkeys with exteriorized
terohepatic circulations were subjected to
ort periods of biliary obstruction by clamping
eir bile T-tubes. Pre- and postobstruction
tes of bile acid synthesis were determined by
e marker-dilution technique after the bile
lt pool was labeled with 14_C- acid and/or the
condary bile salt, deoxycholic acid. After
clamping the T-tube, the bile salt pool was
llected by total biliary diversion until
e marker was completely retrieved or the
terohepatic circulation reestablished, and
e biliary lipid secretion rates and relative
ncentrations were determined. Individual
inary and serum bile salts were also followed
roughout the experiment. Bile acid synthesis
s suppressed in animals obstructed for more
an 6 hr; it remained inhibited for up to 10
after the relief of obstruction. During
struction, most of the bile salt pool was
tained in the liver. In monkeys with reestablished
terohepatic circulation following obstruction,
le salt secretion rates remained suppressed,
ile those of phospholipid and cholesterol were
enhanced. Thus, bile with a decreased cholesterol-holding capacity was secreted for several days after the relief of obstruction.

4275 STUDIES OF HEPATIC CHOLESTEROL SYNTHESIS IN EXPERIMENTAL ACUTE BILIARY OBSTRUCTION. *(E.)* Cooper, A. D.; Ockner, R. K. (Univ. California Sch. Med., San Francisco). *Gastroenterology* 66(4): 586-595, 1974.

Hepatic cholesterol synthesis and response to feedback inhibition was studied in rats 48-hr after selective or complete biliary obstruction. After selective obstruction of the median hepatic lobe, cholesterol synthesis in slices from the obstructed lobe, as measured by incorporation of ^{14}C-acetate, was similar to that after complete biliary obstruction and was 34% greater than that in the unobstructed right lobe. With homogenates, using both ^{14}C-acetate and $^{3}H_2O$ as precursors, synthesis in the obstructed lobe was 90% greater than that in the unobstructed lobe. No significant differences were noted in incorporation of ^{14}C-acetate into $^{14}CO_2$, in tissue cholesterol concentrations, or in uptake of lipoprotein ^{14}C-cholesterol by the lobes. It was suggested that the biliary obstruction interfered with the cholesterol feedback inhibitory mechanism. This interpretation was supported by the additional finding that whereas a 48-hr i.v. infusion of normal quantities of lymph lipoprotein cholesterol almost completely blocked the expected rise in synthetic rate in bile fistula rats, this same infusion had essentially no effect on the increased hepatic cholesterol synthetic rats in animals with complete biliary obstruction. Furthermore, although a 48-hr i.v. infusion of twice normal amounts of lipoprotein cholesterol suppressed synthesis in both lobes of selectively obstructed rats, it did not abolish the relative difference between them. In triparanol-treated rats, complete biliary obstruction caused a greater increase in blood desmosterol than in controls, both absolutely and relative to blood cholesterol. These studies indicate that in acute biliary obstruction, increased precursor incorporation *in vitro* is associated with accelerated net synthesis of cholesterol *in vivo*, and reflects an abnormality in the control of hepatic cholesterol synthesis.

307 ROLE OF BILE ACIDS IN THE ACTIVATION OF
TRYPSINOGEN BY ENTEROKINASE: DISTURBANCE
F TRYPSINOGEN ACTIVATION IN PATIENTS WITH INTRA-
EPATIC BILIARY ATRESIA. *(E.)* Hadorn, B.; Hess,
.; Troesch, V.; Verhaage, W.; Gotze, H.; Bender,
. W. (Dept. Pediatrics, Univ. Berne, Switzerland).
astroenterology 66(4):548-555, 1974.

he effect of bile acids on the activation of tryp-
inogen by the soluble fraction of rat intestinal
omogenates containing enterokinase (EC 3.4.4.8)
as studied. Glycodeoxycholate, 2.5 mM, caused a
.8-fold increase in the velocity of the activation
rocess at low trypsinogen concentrations and a 2-
old increase of the maximal velocity of trypsinogen
ctivation by enterokinase. Sodium taurocholate
ad a similar effect. The same concentration of
glycodeoxycholate caused a decrease of the Michaelis constant for the enterokinase-catalyzed trypsinogen activation: Km was 0.109 mM in the absence of bile acids and fell to 0.015 mM in their presence. The total amount of trypsin formed from a known amount of trypsinogen was also augmented in the presence of bile acids. A similar result was obtained when human pancreatic juice was used as the source of trypsinogen and human small intestinal homogenates as the source of enterokinase. In 3 children with biliary atresia and no bile acids in the duodenal contents, abnormally low trypsin activities were found before and after stimulation of pancreatic function with pancreozymin-cholecystokinin and secretin. Chymotrypsin activity, however, was normal. Evidence was obtained that trypsinogen activation by enterokinase is incomplete in the absence of bile

acids. It is concluded that in the rat and in man bile acids are important for a rapid and complete trypsinogen activation by enterokinase.

4308 A COMPARATIVE STUDY OF THE DISTRIBUTION OF SOLUBLE AND PARTICULATE GLYCYL-L-LEUCINE HYDROLASE IN THE SMALL INTESTINE. *(E.)*

Das, M.; Radhakrishnan, A. N. (Christian Med. Coll. Hosp., Vellore India). *Clin. Sci. Mol. Med.* 46(4):501-510, 1974.

Glycyl-L-leucine hydrolase activity was measured in the soluble and particulate fractions of intestinal mucosa from monkey, (*Macaca radiata*) guinea pig, rabbit, and rat. The specific activity of the soluble enzyme is very high in monkey and guinea pig, and lower in rabbit and rat. The particulate enzymes from all the 4 species show low specific activities and comprise only 1-10% of the total activity. The pH optima in all cases lie in the range 7.6-7.8. The K_m values of the substrate were similar for both soluble and particulate enzyme from monkey and guinea pig, but in the rabbit and rat, the K_m value with the particulate enzyme was higher than with the soluble enzyme. The particulate enzyme activity in all cases was highest in the distal regions of the intestine, whereas the soluble enzyme showed maximal activity in the proximal and middle regions.

4309 CHANGES IN INTESTINAL LACTASE AND ALKALINE PHOSPHATASE ACTIVITY LEVELS WITH AGE IN THE BABOON (Papio papio). *(E.)*

Welsh, J. D.; Russell, L. C.; Walker, Jr., A. W. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Gastroenterology* 66(5):993-997, 1974.

A study of baboons was undertaken to determine whether intestinal enzyme activities decreased with age as they do in some ethnic groups in humans. Eight Olive baboons (*Papio papio*) which had been nursed for up to 6 months by their mothers were killed at 1-36 months of age. The small intestines were divided into 10 equal segments and assayed for disaccharidase, alkaline phosphatase, and leucyl naphthylamidase activities. Lactase and cellobiase values were lower in the duodenum and ileum of 8 to 12-month-old animals than in those 1 to 4 months old. The lowest values all along the intestine were found in the 36-month-old animals. Alkaline phosphatase activity was highest in the 1 to 4-month-old animals, and, after this age, was usually less than half that present in the younger animals. Sucrase, maltase, palatinase, trehalase, and leucyl naphthylamidase activities were essentially similar at all ages. These findings suggest that the low levels of lactase in some human subjects may be a normal age-related phenomenon, as in the baboon.

4310 RADIOLABELED TOXIN FOR STUDYING BINDING OF CHOLERA TOXIN AND TOXOIDS TO INTESTINAL MUCOSAL RECEPTOR SITES. *(E.)*

Peterson, J. W.; Verwey, W. F. (Univ. Texas Med. Br., Galveston). *Proc. Soc. Exp. Biol. Med.* 145(4):1187-1191, 1974.

The binding of choleragen, choleragenoid, and artificial cholera toxoids to intestinal epithelial receptor sites was studied *in vitro* in mucosal homogenates prepared from the small intestines of normal adult guinea pigs. Three concentrations of radiolabeled choleragen were incubated with a series of tubes containing increasing amounts of mucosal homogenate. Increasing levels of radioactivity in the washed homogenate indicated that toxin adsorption increased with increasing concentrations of mucosal homogenate. However, 100% of the labeled toxin was not bound, even when lower concentrations of radiolabeled toxin were added. At the highest concentration of homogenate tested, approximately 50% of the total radioactivity was bound for each of the 3 concentrations of ^{125}I-choleragen added. Binding of ^{125}I-choleragen to mucosal homogenate was inhibited by 50-100 ng/ml of both choleragen and choleragenoid, whereas normal rabbit serum proteins, at comparable and even higher concentrations, failed to inhibit binding. The relative failure of goat immunoglobulin, iodinated by an identical procedure, to bind to the mucosal homogenate also supports the specificity of ^{125}I-choleragen binding. When dilutions of equine antitoxin were incubated with ^{125}I-choleragen prior to the addition of mucosal homogenate, the binding of radiolabeled toxin decreased to a low level as the concentration of antitoxin was increased. The data indicate that cholera toxin binding is highly specific for the toxin and is not inhibited by heterologous protein. In contrast, artificial toxoids, currently under investigation as potential human vaccines, appear to have lost their affinity for the tissue receptor.

4311 THE INFLUENCE OF CHANGING CELL KINETICS ON FUNCTIONAL DIFFERENTIATION IN THE SMALL INTESTINE OF THE RAT. A STUDY OF ENZYMES INVOLVED IN CARBOHYDRATE METABOLISM. *(E.)*

DeBoth, N. J.; Plaisier, H. (Med. Fac., Erasmus Univ., Rotterdam, Netherlands). *J. Histochem. Cytochem.* 22(5):352-360, 1974.

The activity of a number of enzymes involved in carbohydrate metabolism was measured in different cellular compartments of the duodenal epithelium of the rat by microchemical techniques. The enzyme activities were related to different cell positions along crypt and villus and to cell age. Enzyme activities in proliferating, differentiating and functional cell compartments of the intestine of normal rats were compared with those in which the cell kinetics had been modified. The effects of increased proliferative activity within the crypt of normal animals was studied in the intestine during recovery after low radiation doses. The effect of increased lifespan was investigated in germ-free animals. The specific activity of α-glucosidase, present in microvilli, increased considerably during cell differentiation and subsequent cell migration along the villus. Its specific activity remained unchanged in isolated intestinal loops deprived of dissaccharide substrate for 6 weeks. Lactate dehydrogenase and, to a lesser extent, glucose-6-phosphate dehydrogenase had a pattern of activity similar to α-glucosidase. In contrast, hexokinase and isocitrate dehydrogenase were equally distributed among crypt and villus cells and no clear differences were observed with increasing cell age. Increased proliferation in the crypts during recovery after low radiation doses resulted in a marked decrease of α-glucosidase activity in both crypt and villus cells. In the villi of germ-free rats α-glucosidase activity was higher than in the villi of conventional rats. The increased life-span of epithelial cells in germ-free rats had no effect on the level of enzyme activity.

4312 EFFECT OF DEOXYCHOLATE, INDOLE, AND ENDOTOXIN ON ORGAN CULTURES OF RABBIT JEJUNUM.

(E.) Beeken, W. L.; Roessner, K. D.; Krawitt, E. L. (Coll. Med., Univ. Vermont, Burlington). *Gastroenterology* 66(5):998-1004, 1974.

Changes in morphology, protein synthesis, amino acid transport, and brush border enzyme levels produced by deoxycholate (0.01-1.0 mM), *Escherichia coli* lipopolysaccharide (10 and 100 μg/ml), and indole (0.1 and 0.4 M) were studied in an organ culture system. Rabbit jejunum incubated for 24 hr in medium containing 1 mM deoxycholate showed complete loss of villous architecture, dissolution of cell structure, and marked impairment of protein synthesis and amino acid transport, but no significant changes occurred in brush border alkaline phosphatase and sucrase activity. Incubation of jejunal cultures with lower concentrations of deoxycholate, indole, or bacterial endotoxin caused minor morphological alterations, but no functional differences.

4313 THE ROLE OF THE COLON IN THE METABOLISM OF SALICYLAZOSULPHAPYRIDINE.

(E.) Das, K. M.; Eastwood, M. A.; McManus, J. P. A.; Sircus, W. (Western Gen. Hosp., Edinburgh, Scotland). *Scand. J. Gastroenterol.* 9(2):137-141, 1974.

The amount of salicylazosulfapyridine which reaches the colon and the role of the colon in the metabolism of the drug (3-4 g/day p.o.) were studied in 8 patients with a permanent ileostomy after total colectomy, with preservation of rectum in 4, and 2 patients with transverse colostomy. Serum salicylazosulfapyridine concentration and 24-hr urinary excretion of the drug did not alter significantly before surgery and up to 6 months after total colectomy with ileostomy; however, there was a significant decrease in total free sulfapyridine concentration, both in serum and urine, after surgery. Salicylazosulfapyridine concentrations in serum and 24-hr urine were lower in patients with Crohn's disease and ileostomy than in patients with ulcerative colitis and ileostomy, but the results for total free sulfapyridine in serum and urine were the same in both conditions. It appears that only a small proportion of the administered dose of salicylazosulfapyridine is absorbed as unsplit drug from the small intestine. Most of the administered dose reaches the colon, where it is split into its components. After ileostomy there was a significant decrease in drug absorption, so that less than 5% of the administered dose was recovered in the 24-hr urine and the serum concentration was also significantly low.

4314 COMPARISON OF ENDOGENOUS RELEASE OF SECRETIN AND CHOLECYSTOKININ IN PROXIMAL AND DISTAL DUODENUM IN THE DOG.

(E.) Konturek, S. J.; Radecki, T.; Thor, P. (Med. Acad. Krakow, Poland). *Scand. J. Gastroenterol.* 9(2):153-157, 1974.

The relative effectiveness of proximal *versus* distal duodenum in endogenous release of secretin and cholecystokinin was studied in chronic gastric and pancreatic fistula dogs provided with Thiry loops fashioned of upper and lower parts of the duodenum. I.v. infusion of secretin (0.25-16 U/kg/hr) produced a dose-related pancreatic volume flow and bicarbonate secretion that was maximal at a dose of 8 U/kg/hr. I.v. infusion of exogenous cholecystokinin (2-36 U/kg/hr) with a background dose of secretin also resulted in a dose-related pancreatic protein response, with maximal secretion observed for 18 U/kg/hr. Acidification of the proximal duodenal loop produced slightly greater pancreatic bicarbonate response than similar acidification of the distal duodenal loop. The difference in the response obtained with acidification of the loops was statistically significant. Acidification of the proximal and distal duodenal loop resulted in almost equal rates of pancreatic protein outputs, equivalent to that obtained with 2 U/kg/hr of exogenous cholecystokinin, and reached about 30% of the maximal protein output in response to cholecystokinin. Amino acid irrigation of the proximal duodenal loop produced protein output from the pancreatic fistula slightly higher than similar perfusion of the distal duodenal loop. It is concluded that secretin and cholecystokinin releasing capacity/unit length of the duodenum is constant and there is no gradient of releasable intestinal hormones along the duodenum.

4315 HORMONAL STIMULATION OF INTESTINAL DISACCHARIDASE RELEASE IN THE DOG.

(E.) Dyck, W. P.; Bonnet, D.; Lasater, J.; Stinson, C.; Hall, F. F. (Scott White Clin., Temple, Tex.). *Gastroenterology* 66(4):533-538, 1974.

Release of the enteric enzymes -- sucrase, maltase, and lactase -- into the perfused small intestinal lumen of the dog was augmented by i.v. injection of secretin (4.0 U/kg) and cholecystokinin (4.0 Ivy dog U/kg). A direct hormonal stimulation of the intestinal mucosa is considered responsible for the enzyme release, since bile and pancreatic juice were excluded from the perfusion solution. Cholecystokinin exerted a much more pronounced effect on enzyme release than did secretin. Disaccharidase activities in mucosal tissue remained relatively constant after the injection of cholecystokinin.

4316 THE ENZYMATIC CONTENT OF THE SMALL INTESTINE IN THE RATS, AFTER METHOTREXATE TREATMENT.

(E.) Marrone, J. O.; Cantor, D. S.; Cecchetti, C. J.; Costa, J. A. (Profesor Alejandro Posadas Polyclin., Buenos Aires, Argentina). *Acta Gastroenterol. Latinoam.* 5(13):129-132, 1973.

The effect of methotrexate (5 mg/kg i.p. for 3 days) on the intestinal content of disaccharidases and the correlation of this effect with the histological alteration of the small intestinal mucosa were studied in 21 Wistar rats. A control group of 21 rats was injected with normal saline. Lactase concentration averaged 2.00 in the control group and 0.71 in the methotrexate group. Sucrase concentration was 9.27 in the control group and 1.94 in the methotrexate group. Maltase concentration was 41.33 in controls and 16.12 in methotrexate-treated rats. Although the enzymatic defect could not be correlated with tissue changes, methotrexate produced a striking change in all components of the intestinal mucosa. The surface epithelium showed flattening of cells, changing the normal pattern to a cuboid shape. There was also marked alteration of the brush order. The villi were wide and the height was diminished. Crypt cells were flattened, with focal nuclear degeneration and cellular disintegration; the mitotic index was abolished and the lumen of the crypts were dilated and filled with inflammatory cells.

4317 PYRUVATE KINASE ISOZYMES FROM RAT INTESTINAL MUCOSA. CHARACTERIZATION AND THE EFFECT OF FASTING AND REFEEDING. *(E.)* Osterman, J.; Fritz, P. J. (Pennsylvania State Univ. Coll. Med., Hershey). *Biochemistry* 13(8):1731-1735, 1974.

Five electrophoretically distinct zones of pyruvate kinase activity were observed in extracts of jejunal and ileal mucosa from male adult Sprague-Dawley rats. The major form is pyruvate kinase 5 corresponding to the predominant isozyme in rat kidney and the minor isozyme in rat liver. Four of the 5 bands are neutralized by rabbit anti-rat pyruvate kinase 3 (type M). Pyruvate kinase 1 (type L) was not neutralized. Only 4 peaks with pyruvate kinase activity could be resolved by DEAE-Sephadex chromatography and the first 3 peaks had the electrophoretic mobility of pyruvate kinase 5. The fourth peak contained 2 electrophoretically distinct bands, one with the mobility of pyruvate kinase 1 and the other with a mobility between pyruvate kinase 2 and 3. Rat jejunal pyruvate kinase 5 and 1 both displayed sigmoidal kinetics with respect to phosphoenolpyruvate; pyruvate kinase 5 was slightly activated while pyruvate kinase 1 was strongly activated by fructose 1,6-diphosphate. Jejunal pyruvate kinase activity decreased about 50% between 24 and 48 hr after withdrawal of food. When the rats were refed, jejunal pyruvate kinase activity increased and reached a peak 72 hr after refeeding that was about 50% greater than control values. Thereafter, enzyme levels returned to control levels. The changes in pyruvate kinase activity were shown by immunological techniques to be due to changes in enzyme protein. It was demonstrated that all 5 electrophoretic forms of the enzyme were affected similarly by fasting and refeeding.

4318 RECIPROCAL ADAPTIVE CHANGES IN INTESTINAL Na^+ K^+-ATPase AND ADENYL CYCLASE AFTER SMALL BOWEL RESECTION IN THE RAT. *(E.)* Oya, R.; Weser, E. (Univ. Texas Med. Sch., San Antonio). *Gastroenterology* 66(4):757, 1974.

GENERAL

4338 COMPARATIVE STUDY ON TWO LYSOSOMAL-MARKER ENZYMES FROM LIVER AND INTESTINAL MUCOSA. *(E.)* Baglioni, T.; Cavallone, E.; Locatelli, A.; Simonic, T. (Veterinary Univ., Milan, Italy) *Ital. J. Biochem.* 22(4):186-201, 1973.

Properties of 2 lysosomal enzymes, acid phosphatase and β-glucuronidase, of intestinal mucosa were compared with those of liver. Wistar rats were used as the source of the enzymes and the different preparations studied consisted of lysosomal and supernatant fractions. The properties tested were the relative activities of the different fractions and the response of the fractions to various labilizing treatments which facilitated release of enzyme. Supernatant activities for both acid phosphatase and β-glucuronidase, relative to total activity, were higher in intestinal mucosa than in liver. Labilizing treatments with non-ionic detergents (Triton X-100 and Nonidet P40), freezing and thawing, osmotic shock by dilution with water, high sodium chloride concentration, or heat caused release of both enzymes in the liver preparations, particularly in the lysosymal fractions, but not in the intestinal mucosal preparations. The results suggest differences in enzyme molecular structure related to differences in source of tissue.

4339 DEMONSTRATION OF COLLATERAL ARTERIAL FLOW AFTER INTERRUPTION OF HEPATIC ARTERIES IN MAN. *(E.)* Mays, E. T.; Wheeler, C. S. (Price Inst. Surg. Res., Univ. Louisville, Ky.). *N. Engl. J. Med.* 290(18):993-996, 1974.

Of 50 patients who had therapeutic ligation of various hepatic arteries, 20 were routinely evaluated during the postoperative period by angiography and radionuclide scanning. The hepatic arteries in these patients were intentionally occluded to control hemorrhage and tumor growth or as part of "en bloc" resection for cancer. Of the 20, 11 had the right ramus ligated as close to the liver as possible, 5 the left ramus, and in 4 the common hepatic artery was interrupted. Revascularization of the interrupted hepatic artery was noted in all 20 patients. When either the right or left hepatic artery was interrupted, intrahepatic translobular vessels established flow in the ligated system. Such intrahepatic vessels between the right and left rami are not seen in cadaver liver perfusions, nor on arteriograms of normal subjects. Thus, they are probably under neurohumoral control. If the common hepatic artery is interrupted, revascularization occurs through inferior phrenic, pancreaticoduodenal and intercalary *de novo* arteries. Hepatic arterial flow was reconstituted distal to the ligature as early as 10 hr after interruption and increased with time. Liver necrosis after hepatic artery ligation in man is rare if portal-vein flow and oxygenation are optimum until arterial flow is reconstituted. The rapidity with which revascularization occurs suggests that the dearterialization of the liver in an effort to produce necrosis of metastastic and primary hepatic tumors will have only a temporary effect on tumor growth, and would be of value mainly for relieving symptoms produced by local tumor growth.

4340 IN VIVO LOCALISATION OF RADIOLABELLED ANTIBODIES TO CARCINOEMBRYONIC ANTIGEN IN HUMAN COLON CARCINOMA GRAFTED INTO NUDE MICE.

(E.) Mach, J. P.; Carrel, S.; Merenda, C.; Sordat, B.; Cerottini, J. C. (Ludwig Inst. Cancer Res., Lausanne, Switzerland). *Nature* 248(5450): 704-706, 1974.

Volumes of 0.2 ml containing about 2 μg ^{131}I-labeled, purified goat antibody against human carcinoembryonic antigen and 200 μg normal goat 7S globulin were injected into nude mice (Balb/c Nu-Nu) bearing subcutaneous grafts of human colon carcinomas and also into control nontumor-bearing mice. After 2 to 6 hr, the radioactivity, as detected by external scintillation scanning, was homogeneously distributed throughout both tumor-bearing mice and controls. After 1 day, however, radioactivity began to localize in the tumor area, giving optimal contrast by the third day. The animals were then dissected and separate organs and pieces of the body were weighed and measured for radioactivity. For a 24 g mouse, for example, 40% of the total radioactivity was concentrated within the 1.8 g tumor which the mouse bore. The smallest tumor nodule detectable by scanning was 200 mg. To test for possible nonspecific accumulation of injected globulins in the extravascular space and necrotic regions of the tumor, additional experiments were carried out in which antibody localization was studied after simultaneous injection of ^{131}I-labeled antibody and ^{125}I-labeled normal goat 7S globulin, or of the two materials with reversed labels. The results showed that in the tumor the concentration of antibody was more than twice that of normal 7S globulin, whereas in normal tissue the antibody was present in lower concentration than the normal globulin. When a specificity index was calculated by dividing the ratio of tumor antibody concentration: normal tissue antibody concentration by the same ratio for normal 7S globulin, significantly positive results were obtained for all colon carcinomas tested. In contrast, when the same experiment was performed in C57BL/6 mice bearing transplanted EL4 solid lymphoma, specificity indices were not significant. The specificity of the antibody localization decreased with the presence of necrotic tissue within the tissue. However, a nonnecrotic fragment showed a very high specificity index and when cells from disrupted tumor fragments were washed with buffered saline, 55% of the antibody radioactivity remained bound to the cells compared with only 15% of the normal 7S globulin radioactivity.

4341 IMMUNOGLOBULINS IN FECES FROM INFANTS FED HUMAN OR BOVINE MILK. *(E.)*

Haneberg, B. (Univ. Bergen, Sch. Med., Norway). *Scand. J. Immunol.* 3(2):191-197, 1974.

In feces from infants fed human milk, the concentration of human immunoglobulins, particularly I_gA, were higher than in feces from infants fed cow's milk. The same kind of difference between the two feeding groups, at 1 month of age, was also evident for the antibody activity in feces, using agglutinins to rabbit erythrocytes as markers. A good correlation between levels of antibody in milk and in feces of infants receiving that milk indicated that part of the antibodies in feces was derived from the milk. No difference in agglutinin activity was noted, however, in infants 2-3 months of age. The higher antibody activity in feces of infants receiving human milk could mean that the infants' own intestinal antibodies are better preserved, that their production is stimulated, or that human milk antibodies pass through the intestinal tract. Evidence supporting the last interpretation was provided by the finding that isoagglutinins in human milk to blood group antigens A and B were recovered in feces from infants receiving this milk, regardless of the infants' own blood group. Gel filtration studies, as well as inhibition of agglutination and antiglobulin test, gave evidence that IgA was largely responsible for the fecal agglutinin activity. Unlike human milk in which IgM also reacts with rabbit erythrocytes, only IgA in the fecal extracts had such activity. IgA antibodies in human milk thus retained some of their activity with passage through the infant gut.

4342 A STUDY OF INTERCELLULAR SPACES IN THE RABBIT JEJUNUM DURING ACUTE VOLUME EXPANSION AND AFTER TREATMENT WITH CHOLERA TOXIN. *(E.)*

DiBona, D. R.; Chen, L. C.; Sharp, G. W. G. (Massachusetts Gen. Hosp., Boston). *J. Clin. Invest.* 53(5):1300-1307, 1974.

The effects of acute volume expansion and of intraluminal administration of cholera toxin (10 μg) were examined in rabbit jejunum. Acute volume expansion reversed the normal reabsorptive flux of water and caused significant fluid secretion. Phase and electronmicroscopic examination of the jejunal epithelium showed that marked distension of the intercellular spaces had occurred. Examination of the jejunal epithelium after treatment with cholera toxin showed that in association with high rates of fluid secretion, the intercellular spaces were extremely small and lateral membranes of adjacent cells were in close apposition to one another. Thus the mechanisms of fluid secretion in these 2 situations appear to be quite different. The secretion associated with volume expansion, and accompanied by a rise in venous pressure and bullous deformations of terminal junctions, could be due to hydrostatic pressure, applied through intercellular channels. The secretion of cholera appears to be unrelated to hydrostatic pressure and is more likely due to body-to-lumen active ion transport.

4343 THE INFLUENCES OF MECHANICAL FACTORS ON INTESTINAL LYMPH FLOW AND THEIR RELATIONSHIP TO OPERATIONS FOR CARCINOMA OF THE INTESTINE. *(E.)* Ackerman, N. B. (Menorah Med. Ctr., Univ. Missouri, Kansas City). *Surg. Gynecol. Obstet.* 138(5):677-682, 1974.

The effects of various mechanical factors on the flow of lymph from the intestines were studied in mongrel dogs. Manual massage of the intestines caused an immediate highly significant increase in lymph flow. When pressures within the lumen of the intestines were elevated slightly above normal by the introduction of air, lymph flow increased markedly. Generally, as intraluminal pressures rose further to extremely high levels (60 mm Hg), the initially elevated rates of lymph flow decreased. As intraluminal pressures were decreased, a secondary rise in lymph flow often occurred. Hyperperistalsis, produced by direct electrical stimulation, also caused rapid, dramatic increases in lymph flow, but since intraluminal pressures rose during periods of hyperperistalsis, the mechanical effects of muscular activity alone could not be determined. It is probable that the decreased survival rate of patients with obstructing carcinomas of the colon, is partly due to the higher flow of lymph from the area of the carcinoma causing an increased dissemination of cancer cells. Thus, all diagnostic, preparatory, and operative procedures which may increase pressures on the intestinal wall or within the lumen should be minimized. These procedures include palpation of the abdomen, barium and air contrast enema studies, colonoscopy, cleansing enemas and cathartics, and excessive handling and palpation of the carcinoma and adjacent intestine during the operation.

4344 DUODENAL VILLUS AREA AND EPITHELIAL CELLULAR MIGRATION IN CONVENTIONAL AND GERM-FREE CHICKS. *(E.)* Cook, R. H.; Bird, F. H. (Dept. Anim. Vet. Sci., Univ. Maine, Orono). *Poult. Sci.* 52:2276-2280, 1973.

The morphological and epithelial cellular kinetic differences noted in the small intestine of older germ-free animals were studied to see if they would manifest themselves in week-old Leghorn chicks. By day 7, the villus area was significantly larger and the crypt depth was significantly deeper in the conventional chicks than in the germ-free chicks. The active proliferative cellular pool in the crypts of the conventional checks was more than twice the size of the analogous proliferative compartments in the germ-free chicks. In addition, the rate of epithelial cellular migration from the crypt villus junction to the villus tip was approximately 1.7 times faster in the conventional chicks. A bacteria-induced extrusion process may have had a significant effect on epithelial cellular kinetics and duodenal mucosal growth processes in the young chicks.

4345 IMMUNOGLOBULINS ON THE SURFACE OF HUMAN APPENDIX LYMPHOCYTES. *(E.)* Jubert, A. V.; McBride, C. M.; Mavligit, G.; Gutterman, J. U.; Hersh, E. M. (Univ. Texas, M. D. Anderson Hosp. Tumor Inst., Houston). *Immunol. Commun.* 3(1):1-9, 1974.

The proportion of appendix and peripheral blood lymphocytes with IgM, IgG, IgA, and IgE cell surface determinants was measured by membrane immunofluorescence in 14 patients with primary carcinomas. IgM was found in 9.2% of appendix lymphocytes compared with 3.5% of simultaneously collected peripheral blood lymphocytes. In contrast, IgG was found on 6.3% of peripheral blood lymphocytes compared with only 3.0% of appendix lymphocytes. There was no difference in the number of cells with IgA or IgE determinants between the two populations. Since surface-bound immunoglobulins are a marker of B-lymphocytes (B cells) in man, these results indicate that a substantial proportion of human appendix lymphocytes are B cells. The higher level of IgM, if confirmed by further studies, would point to some central role for the human appendix lymphocyte immunologic reactivity.

4346 MEASUREMENT OF PANCREATIC BLOOD FLOW IN DOG BY ^{133}Xe CLEARANCE TECHNIQUE. *(E.)* Ercan, M. T.: Bor, N. M.; Bekdik, C. F.; Oner, G. (Dept. Nuclear Med., Hacettepe Univ., Ankara, Turkey). *Pfluegers Arch.* 348(1):51-57, 1974.

The water/gas, plasma/gas, erythrocyte/gas and pancreas/gas partition coefficients of ^{133}Xe were measured at 37°C in dog tissues. The pancreas/blood partition coefficients were calculated from these values and plotted as a function of hematocrit. The ^{133}Xe pancreas/blood partition coefficient in the normal range was 1.2 ml/g. Pancreatic blood flow was determined in each case by injecting ^{133}Xe into the pancreaticoduodenal artery (mean 106.8 ml/100 g/min). Pancreatic blood flows were also determined by injecting the tracer into the tissue of head, body, and the tail of pancreas. The means were 62.4, 85.7, and 67.1 ml/100 g/min, resp. The mean pancreatic blood flow obtained by intra-arterial injection was significantly different from the results obtained by injecting ^{133}Xe into the head or tail, but was not statistically different from that obtained by injection into the body of pancreas. The results obtained by injecting ^{133}Xe into the head, body, and tail of the pancreas were not significantly different from one another. The large network of anastomoses between pancreatic blood vessels and the vasculature of adjacent organs may partially account for this discrepancy.

4347 GLUCAGON INDUCES PREMATURE STRUCTURAL DIFFERENTIATION OF FETAL HEPATOCYTES. *(E.)* Chiu, H. F.; Phillips, M. J. (Toronto Gen. Hosp., Canada). *Lab. Invest.* 30(3):305-310, 1974.

The effects of glucagon on the liver of fetal rats have been studied ultrastructurally. On the 20th day of gestation females were laparotomized and glucagon was injected through the uterine wall and i.p. into 4 fetuses of each pregnant rat (0.0125 mg/g/fetus). Within 6 hours after glucagon administration, immature glycogen-filled fetal hepatocytes showed significant strucutral differentiation. Glycogen depletion, increase in ribosome-coated vesicles, peroxisomes, and primary lysosomes, hypertrophy of the Golgi apparatus, and formation of secondary lysosomes were observed. In addition, a tubular anastomosing network of smooth membranes appeared in the hepatocytes. These cytologic changes were similar to those that ensue physiologically following birth, and coincide with known biochemical effects of glucagon in the fetal liver: induction of glycogenolysis, gluconeogenesis, and enzyme activation. Glucagon may be implicated in the differentiation of fetal liver cells in the perinatal period.

4348 ON THE CORROSIVE PROPERTIES OF BILE AND PANCREATIC JUICE ON LIVING TISSUE IN DOGS. *(E.)* Wickbom, G.; Bushkin, F. L.; Linares, C.; Dragstedt, L. R. (Coll. Med., Univ. of Florida, Gainsville). *Arch. Surg.* 108(5):680-684, 1974.

Regurgitation of bile, pancreatic juice, or duodenal secretions into the stomach or esophagus occurs under certain conditions and has been incriminated as the cause of gastritis and alkaline esophagitis. In an experimental study in dogs, bile was diverted into the stomach and into the ileum for 4 months without producing substantial mucosal changes. In similar experiments, pancreatic juice was diverted into the stomach and colon for 1 to 12 months, again without producing mucosal damage. The parenchyma of the spleen and kidney was exposed to concentrated gallbladder bile for long periods without undergoing substantial changes. These findings suggest that individual duodenal secretions produce little or no damage on contact with the gastrointestinal mucosa of the dog or on the parenchyma of the spleen or kidney.

4349 ISOLATION AND CHARACTERISTICS OF GUT MUCOSAL LYMPHOCYTES. *(E.)* Rudzik, O.; Bienenstock, J. (McMaster Univ. Med. Ctr., Hamilton, Canada). *Lab. Invest.* 30(3):260-266, 1974.

Gut mucosal lymphocytes, exclusive of Peyer's patch cells, were isolated from New Zealand White rabbits by a newly devised technique. An average yield of 37×10^6 lymphoid cells were obtained from 10 g of ileum after passage through a glass bead column and a discontinuous density gradient. The viability was always greater than 95% and the cell suspension was contaminated with less than 1% of epithelial cells. The majority (78%) of the cells were small and medium sized lymphocytes. However, large lymphocytes and blast cells were also present. The cells remained viable in cultures for up to 72 hr *in vitro* and incorporated ^{3}H-uridine and ^{3}H-thymidine. Only 1% of the cell population contained intracellular immunoglobulin as judged by immunofluorescent techniques. This was mainly of the IgA class. On an average, 25% of the lymphoid cells contained metachromatic cytoplasmic granules. The granules were stained at low pH with Alcian Blue, metachromatically with toluidine blue, and nonspecifically with fluoresceinated goat anti-rabbit immunoglobulin reagents. Since these granular lymphoid cells were found only in the epithelium (rarely in lamina propria), it is assumed that these cells were isolated from the epithelium. These techniques have been applied to the guinea pig and to man with equal success in terms of yield and recovery. The availability of mucosal lymphocytes for direct study is a crucial step toward the investigation and interpretation of mucosal cellular immunity.

4350 EFFECT OF PHARMCOLOGICAL DOSES OF GLUCAGON ON HUMAN HEPATIC CIRCULATION. *(Ger.)* Wicklmayr, M.; Dietze, G.; Czempiel, H.; Hepp, K. D.; Mehnert, H.; Henftling, H. G. (Schwabing Hosp., Munich, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:933-936, 1973.

DIAGNOSTIC PROCEDURES

4364 CLINICAL EVALUATION OF THE ^{14}C FAT ABSORPTION TEST. *(E.)* Burrows, P. J.; Fleming, J. S.; Garnett, E. S.; Ackery, D. M.; Colin-Jones, D. G.; Bamforth, J. (Southampton Gen. Hosp.). *Gut* 15(2):147-150, 1974.

The absorption of ^{14}C-labeled glyceryl tripalmitate was tested in 62 patients by determining the maximum specific activity of CO$_2$ in the breath after an oral dose. A significant correlation with fecal fat excretion was found. The absorption of ^{14}C labeled palmitic acid was tested subsequently in 54 patients. In cases of pancreatic steatorrhoea, normal absorption of palmitic acid with impaired absorption of glyceryl tripalmitate was found, whereas in most patients with coeliac disease the absorption of both substances was depressed to the same extent.

4365 ENDOSCOPIC AND BIOPSY CRITERIA FOR THE DIAGNOSIS OF ESOPHAGITIS WITH A FIBEROPTIC ESOPHAGOSCOPE. *(E.)* Kobayashi, S.; Kasugai, T. (Aichi Cancer Ctr. Hosp., Nagoya, Japan). *Am. J. Dig. Dis.* 19(4):345-352, 1974.

Endoscopic and biopsy criteria for the diagnosis of esophagitis with a fiberoptic esophagoscope were introduced and a good correlation between them was reported in 144 patients. In 96 of the patients, there was nonspecific esophagitis in esophagoscopy and the remaining 48 patients had no endoscopic abnormalities. Erosion and ulceration were reliable endoscopic signs of esophagitis, with histological confirmation in every case. An endoscopic finding of erythema alone was of less value. A pronounced ingrowth of the lamina propria with associated capillaries into the squamous epithelium represents esophagitis and is often associated with an erythematous mucosal change on endoscopy. It has been emphasized that this may be demonstrated even without the whole of the lamina propria in the biopsy specimen. A histological diagnosis of esophagitis was made in 90% of the patients with endoscopic esophagitis. Thus the criteria introduced here seem to be acceptable for the diagnosis of esophagitis from endoscopic biopsy specimens.

4366 FALSE-NEGATIVE ^{75}SE-SELENOMETHIONINE SCANS IN PRIMARY LIVER CANCER. *(E.)* Kew, M. C.; Geddes, E. W.; Levin, J. (Johannesburg Hosp., South Africa). *J. Nucl. Med.* 15(4):234-236, 1974.

Selenium-75-selenomethionine and ^{99m}Tc-sulfur colloid scans were performed in 45 Southern African blacks with proven primary cancer of the liver and 28 patients with other space-occupying hepatic lesions. In 6 of the cancer patients, the defect or defects visible on the ^{99m}Tc-sulfur colloid scan were not seen on the ^{75}Se-selenomethionine scan, and in 17 patients they had partially disappeared. In the remaining 22 cancer patients and the 28 control patients, the 2 scans were identical. The high incidence of failure of uptake of ^{75}Se-selenomethionine by the tumor is attributed to the anaplastic nature of the neoplasm and the frequency with which tumor necrosis occurs in Southern African blacks with primary cancer of the liver.

4367 RADIOLOGIC DIAGNOSIS OF ILEAL CARCINOID TUMOURS. *(E.)* Boijsen, E.; Kaude, J.; Tylen, U. (Dept. Diagnostic Radiol., Univ. Lund, Sweden). *Acta Radiol. Diagn., Stockh.* 15(1):65-82, 1974.

Nine men and 6 women, aged 32-75 yr, with proven carcinoid tumors of the ileum were examined over a period of 7 years. All of the carcinoid tumors were in the terminal part of the ileum. All patients had metastases in the mesenteric lymph nodes and 11 had metastases in the liver. Calcifications located in the center of the retracted mesentery or close to it were demonstrated in 7 patients. In 9 of 12 patients examined, the degree and type of dilation of the distal ileal loops differed. Vascular changes at superior mesenteric angiography suggested a carcinoid neoplasm of the ileum in 14 of the patients. Arterial wall infiltration, either smooth or irregular, was invariably present and ranged from slight narrowing to complete occlusion. Totruous arteries representing collaterals were observed in 14 patients. Accumulation of contrast medium within the growth was marked in 3 and slight in 4 patients; both the primary growth and local metastases were hypervascular. Hepatic metastases were present in 9 out of 12 patients on whom celiac or hepatic angiography was performed. In 7 of these patients metastases were highly vascularized. An angiographic diagnosis cannot be made until the ileal carcinoid has extended to the mesentery and infiltrated the lymph nodes.

4368 TRYPSIN AND CHYMOTRYPSIN IN DUODENAL ASPIRATE AND FAECES IN RESPONSE TO SECRETIN AND CHOLECYSTOKININ-PANCREOZYMIN. *(E.)* Sale, J. K.; Goldberg, D. M.; Thjodleifsson, B.; Wormsley, K. G. (Roy. Hosp., Sheffield, England). *Gut* 15(2):132-138, 1974.

The secretion of trypsin and chymotrypsin into the duodenum in response to secretin (1.0 clinical U/kg i.v.) and cholecystokinin-pancreozymin (1.0 Ivy U/kg i.v.) was compared with fecal excretion of the enzyme in 47 subjects undergoing clinical investigation of pancreatic exocrine function. There was significant correlation between chymotrypsin outputs in duodenal aspirate and feces. In 53% of the subjects the fecal content of chymotrypsin during the first 6 hr was greater than duodenal aspirate output, and the proportion increased to 74% with the total 24-hr collection. Fecal output of less than 1/2 the duodenal output of chymotrypsin was found in only 3 subjects. The relation between duodenal and fecal outputs was not as good for trypsin. In the majority of cases trypsin output was less in feces than in duodenal aspirate, both in the 6-hr (81% of patients) and 24-hr collections (72% of patients). When the fecal content of trypsin was high, pancreatic capacity to secrete trypsin was also high; however, the converse was not necessarily true since very low levels of tryptic activity were found in subjects with normal capacity to secrete trypsin. These results indicate that fecal excretion of chymotrypsin following stimulation with secretin plus cholecystokinin-pancreozymin is a reliable index of pancreatic enzyme-secretory capacity.

4369 DIAGNOSTIC SIGNIFICANCE OF THE TREHALOSE TOLERANCE TEST IN MALABSORPTION SYNDROMES.

(Ger.) Bolte, J. P.; Schonhage, P.; Forster, E.; Knolle, J.; Meyer zum Buschenfelde, K. H. (2nd Med. Clin., Univ. Mainz, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1303-1307, 1972.

Absorption of glucose, trehalose, lactose, and sucrose was studied on 58 patients by measuring blood sugar levels before and for 15-180 min after p.o. administration of 50 g of each of the sugars. These patients had Crohn's disease (8 cases), ulcerative colitis (11), malabsorption (6), cirrhosis (6), chronic pancreatitis (7), and miscellaneous gastrointestinal disorders (20) including peptic ulcer, generalized amyloidosis, Reiter's disease, abdominal vascular disorders, Billroth II gastroenterostomies, and intestinal shunt surgery performed for obesity. Of the disaccharides, approximately equal quantities of lactose and trehalose were absorbed while the quantity of sucrose absorbed was higher although it contains only 1 molecule of glucose. Lactose intolerance occurred in almost all of the disease states investigated, whereas trehalose intolerance was found primarily in malabsorption, ulcerative colitis, and Crohn's disease and sucrose intolerance occurred in malabsorption. These findings indicate that trehalose intolerance or malabsorption, either alone or in combination with other disaccharide intolerances, is rare. Trehalose intolerance is more useful than lactose intolerance in the diagnosis of primary malabsorption since lactose intolerance can occur as an incidental finding in patients with a great variety of primary diseases.

4370 MECHOLYL ESOPHAGOGRAPHY.

(E.) Ennis, J. T.; Lewicki, A. M. (Peter Bent Brigham Hosp., Boston, Mass.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):241-244, 1973.

Administration of methacholine s.c. combined with cinefluorography offers an easy and accurate assessment of achalasia. A positive response to an initial 2.5 mg dose may occur within 2-3 min and is seen as a lumen-obliterating contraction of the esophagus with reflux of barium into the patient's mouth. If contraction does not occur, the dosage can be adjusted upward in 2.5 mg increments to as much as 10 mg to achieve a response. The esophageal response of achalasia patients to methacholine is evidence that the neuromuscular disorder affects not only the cardia but the distal 2/3 of the esophagus. The part of the swallowing mechanism under voluntary control is seen as normal in these patients. Cinefluorography is indispensable, as the degree of esophageal dilation has an effect on response, and manometric studies alone may yield false-negative results in a grossly dilated, denervated esophagus. Methacholine stimulation serves to distinguish achalasia from other causes of esophageal dilation such as scleroderma, benign peptic stricture, and diffuse esophageal spasm. A positive methacholine response has also been noted in a few patients with infiltrating carcinoma of the esophagus. This is caused by complete destruction of the myenteric plexus to the level of the aortic arch.

4371 PRELIMINARY RESULTS OF LYMPHOGRAPHY OF THE HUMAN STOMACH: A METHOD FOR VISUALIZING GASTRIC LYMPH NODES BY ENDOSCOPIC INJECTION OF LIPIODOL ULTRAFLUID.

(Ger.) Schacht, U.; Junemann, A.; Becker, H. J.; Huth, F.; Moschinski, D.; Palomba, P. P. (Inst. Med. Radiol., Univ. Dusseldorf, Germany). *Dtsch. Med. Wochenschr.* 99(13):616-618, 1974.

Lipiodol Ultrafluid was injected into the gastric submucosa under endoscopic control to visualize gastric lymph nodes in 7 patients with stomach cancer, 8 with stomach ulcers, and 3 with no gastric abnormalities. All diagnoses were confirmed by biopsy and at operation. In all 3 controls the left and right caudal lymph nodes in the stomach, the pancreaticolienal lymph nodes, and the celiac lymph nodes were visualized after 12 hr. The contrast medium remained in the wall of the stomach without reaching the surrounding lymph nodes in 4 of the 8 patients with stomach ulcers, while contrast medium accumulated in the regional lymph nodes in 6 of the 7 patients with stomach cancer. Lymph node metastases were diagnosed histologically in 3 of these 6 patients. Pathological examinations of resected stomachs, performed 2-10 days after lymphography, revealed a moderately acute inflammatory reaction in the submucosa in 1 case and smaller, circumscribed areas of bleeding near the site of injection in 2 cases. No severe inflammation, ulceration, or other side reaction was observed.

4372 THE STRUGGLING ANTRUM: A NEW SIGN OF PERIGASTRIC MALIGNANCY.

(E.) Keller, R. J.; Khilnani, M. T.; Wolf, B. S. (Mount Sinai Hosp., New York, N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):300-310, 1973.

Subtle but analyzable changes occur in the appearance of the antrum during filling and emptying whenever a portion of the wall is fixed, particularly as a result of increased infiltration by carcinoma of the pancreas. Abnormalities of distensibility include pseudoloculation and flattening and ridging. Abnormalities demonstrated during the contraction phase include asymmetry and eccentricity, specific alteration of the slopes of the peristaltic wave, fixation, angulation, elevation, and mucosal fold changes. These abnormalities of antral distensibility and motor activity reflect the attempts by the uninvolved portion of the antrum to maintain adequate mechanical function. In the absence of other roentgen findings, the changes may be sufficient to suggest the diagnosis of perigastric tumor. Abnormalities in the peristaltic pattern may also be seen in intrinsic neoplasms of the antrum. Absence of mucosal ulceration or destruction would exclude an intrinsic process.

4373 A METHOD FOR THE DEMONSTRATION OF THE MUCOSAL PATTERN OF THE DUODENAL CAP.

(E.) Kabakian, H. A. (American Univ. Med. Ctr., Beirut,

Lebanon). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):311-315, 1973.

A technique is described to demonstrate, in the prone position, the mucosal pattern of the duodenal cap which is situated high under the ribs or is obscured by the overlying barium-filled antrum. The patient assumes the prone oblique or lateral position and a pneumatic compression paddle is placed at a distance caudad to the cap. Following deep inspiration, the cap comes to lie over the center of the paddle. The patient is then asked to hold his breath in deep inspiration, while the pneumatic paddle is inflated and the required degree of compression obtained for visualization of the mucosal pattern.

4374 ULCERATIVE AND GRANULOMATOUS COLITIS: VARIATIONS IN OBSERVER INTERPRETATIONS AND IN ROENTGENOGRAPHIC APPEARANCE AS RELATED TO TIME.

(E.) Nelson, J. A.; Margulis, A. R.; Goldberg, H. I.; Fenlon, J. W.; Lawson, T. L.; Amberg, J. R. (Univ. California Sch. Med., San Francisco). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):369-374, 1973.

Examination by 3 radiologists of 32 roentgenograms of confirmed granulomatous colitis yielded a unanimous correct diagnosis in 9 cases and a unanimous incorrect diagnosis of ulcerative colitis in 5. Three months later the same radiologists were given 32 ulcerative colitis films and 18 of the granulomatous colitis films from the first series. A unanimous correct diagnosis of ulcerative colitis was made in 16 cases, whereas a unanimous correct diagnosis of granulomatous colitis was made in only 6. In 3 cases there was unanimous incorrect diagnosis of ulcerative colitis as granulomatous colitis; in 7 there was unanimous incorrect diagnosis of granulomatous colitis as ulcerative colitis. Unanimous correct readings of granulomatous colitis were most often influenced by findings of terminal ileum disease, right-sided colonic disease, deep ulcers, and fistula. Criteria responsible for both correct and incorrect diagnosis of ulcerative colitis were total or left-sided involvement, rectal disease, shallow ulcers, concentric involvement, and totally contracted colon. Over a period of 1 month to 3 yr, 3 cases of granulomatous colitis showed development of an ulcerative colitis pattern on roentgenograms, but these changes did not persist. In 2 cases of ulcerative colitis there was inconclusive evidence of evolution into granulomatous colitis. These findings emphasize the necessity of basing diagnosis of colitis on all current and previous roentgenographic and pathological data.

4375 FILLING OF LIEBERKUHN'S CRYPTS IN THE COLON DURING CONTRAST EXAMINATIONS: A CONTRIBUTION TO THE DIFFERENTIAL DIAGNOSIS OF COLITIS.

(Ger.) Zwad, H.-D. (Med. Coll., Lubeck, Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 120(3):278-283, 1974.

A survey made of the results of barium contrast examinations of the large intestine in 100 children who were considered to have normal findings showed that filling of Lieberkuhn's crypts occurred in 31. All but one of these children were over 1 yr old. Fine saw-toothed irregularities were observed in the contours of the large intestine when the intestine was half full. These irregularities disappeared completely when the intestine was full. After partial evacuation, the saw-toothed irregularities reappeared. Each one measured about 1 mm with about 10-15/cm intestine. These changes were observed in all parts of the large intestine, but were most common in the descending, transverse, and sigmoid colon. Histories and clinical findings showed no evidence of ulcerative colitis. Proctoscopic findings were normal in all 4 patients examined, as were mucosal biopsies in the 2 patients studied. No signs of inflammation were detected and filling of Lieberkuhn's crypts was not associated with constipation. It is concluded that the filling of Lieberkuhn's crypts is a normal finding in children. In contrast to Lieberkuhn's crypts, the ulcerations visualized in ulcerative colitis are irregular in shape and size and the distance between them varies. Unlike Lieberkuhn's crypts, these ulcers are visualized when the intestine is full.

4376 ARTERIOGRAPHIC DIAGNOSIS OF INTESTINAL ADHESIONS.

(Fr.) Fays, J.; Regent, D.; Donner, J.; Bessot, M.; Treheux, A. (Reg. Hosp. Ctr., Nancy, France). *Ann. Radiol. (Paris)* 17(1):65-70, 1974.

Selective superior mesenteric arteriograms from 30 patients with adhesions of the small intestine are analyzed. The diagnosis was confirmed by laparoscopy (4 cases) or laparotomy (26 cases). Malformations of the intestinal arteries which were observed consisted of (1) curvilinear deformations, most often involving the ileal artery; (2) a "bayonette" course in which the ileal artery followed a zig-zag path showing adhesion of the mesentery and the artery which it contained; (3) a recurrent course found in 3 patients; and (4) a pseudotumoral appearance of the superior mesenteric artery, found in 2 patients. The latter deformation resulted from organized hematomas behind the mesentery with loops of the intestine adhering to the periphery of this inflammatory mass. In the capillary stage adjacent loops of the intestine were clustered together and bound to one another. In later stages the veins were displaced in the same manner as the satellite arteries. A profile view, made in 3 cases, revealed that the distal part of the superior mesenteric artery was adherent to the anterior wall of the aorta and the ileal arteries, which followed a sinusoidal course, were displaced backwards. It is emphasized that these arteriographic features are not specific for intestinal adhesions but may be found in other abdominal lesions in which the mesentery is involved. These include mesenteric cysts, peritoneal carcinomas, common mesentery, hernias, and vascular changes secondary to an enteroplasty.

4377 THE AMYLASE-CREATININE CLEARANCE RATIO. DIAGNOSTIC PARAMETER OR PHYSIOLOGIC PHENOMENON?

(E.) Dreiling, D. A.; Leichtling, J. J.;

anowitz, H. D. (Mt. Sinai Hosp., New York, N.Y.). *m. J. Gastroenterol.* 61(4):290-296, 1974.

nalysis was made of serum amylase, urinary amylase nd derived amylase/creatinine clearance data in 377 atients without pancreatic disease, 177 with acute ancreatitis, 167 with chronic pancreatitis and 52 ith pancreatic cancer. Patients without pancreatic isease were divided in 2 groups, first, normal con-rols, and second, differential diagnostic cases com-rising acute conditions as acute cholecystitis, acute ppendicitis, and perforated duodenal ulcers. These groups presented similar means and similar ranges or all 3 parameters. The limits of normalcy as erived from these 2 groups were serum amylase, 200 g%; urinary amylase, 1,200 mg%; and amylase/ reatinine clearance ratio, 4.0. In acute pancrea-itis patients, the mean values were serum amylase, 52 mg%; urinary amylase, 2,491 mg%; and amylase/ reatinine clearance ratio, 14.5, significantly above he limits. Data for patients with chronic pancrea-itis or pancreatic cancer fell within the range for atients without pancreatic disorder. Thus the deter-ination of amylase in the blood and urine has little iagnostic value in these cases, nor does the calcu-ation of the amylase/creatinine clearance ratio. acroamylasemia was encountered in 8 patients and was haracterized by a high serum amylase, low urinary mylase, and very low, below 1%, amylase/creatinine learance ratio. These data suggest that the simul-aneous determination of serum amylase, urinary amy-ase, and the calculation of the amylase/creatinine atio increased the diagnostic significance of amylase alues.

378 INTRAVENOUS CHOLEGRAPHY AND PERORAL CONTRA-CEPTIVES. A PRELIMINARY REPORT. *(E.)* indgren, P.; Saltzman, G. F.; Zeuchner, E. (Natl. oard Health Welfare, Stockholm, Sweden). *Acta Radiol. Diagn.] (Stockh.)* 15(2):217-224, 1974.

379 ACCURACY OF DIAGNOSTIC TOOLS IN MALIGNANT HEPATIC LESIONS. A COMPARATIVE STUDY USING ERUM TESTS, SCINTISCANNING, AND LAPAROTOMY. *(E.)* lmersjo, O.; Bengmark, S.; Hafstrom, L.; Rosengren, . (Dept. Surg., Roentgenology, Univ. Goteborg, Swe-en). *Am. J. Surg.* 127(6):663-668, 1974.

380 RADIOIMMUNOASSAY OF α-FETOPROTEIN. I. TECH-NIQUE AND SERUM LEVELS IN THE NORMAL ADULT. *E.)* Masseyeff, R.; Bonet, C.; Drouet, J.; Sudaka, .; Lalanne, C. (Sch. Med., Nice, France). *Digestion* 0(1):17-28, 1974.

381 CLINICAL APPLICATION OF ISOAMYLASE ANALYSIS. *(E.)* Berk, J. E.; Fridhandler, L. (Coll. ed., Univ. California, Irvine). *Gastroenterology* 6(4):665, 1974.

382 CARCINOEMBRYONIC ANTIGEN. *(E.)* Darani, M.; Dubin, A.; Villa, F.; Szanto, P.; Steigmann, . (Cook County Hosp., Chicago, Ill.). *Gastroenterol-gy* 66(4):680, 1974.

4383 VALUE OF COLONOSCOPY IN THE INVESTIGATION OF INFLAMMATORY BOWEL DISEASE. *(E.)* Das, K. M.; Farid, T.; Berkowitz, J. M. (Nassau County Med. Ctr., East Meadow, N.Y.). *Gastroenterology* 66(4):681, 1974.

4384 HEPATITIS B ANTIBODY: DETECTION WITH A SOLID PHASE RIA AND QUANTIFICATION IN HUMAN GAMMA GLOBULIN. *(E.)* Efrusy, M. E.; Ginsberg, A. L. (George Washington Univ. Med. Ctr., Washington, D.C.). *Gastroenterology* 66(4):688, 1974.

4385 CLINICAL VALUE OF ESOPHAGEAL MANOMETRY. *(E.)* Espiritu, C. R.; Camara, E.; Van Devere, G. (Mt. Sinai Med. Ctr., Miami Beach, Fla.). *Gastroenterology* 66(4):688, 1974.

4386 THE METHEMALBUMIN TEST FOR HEMORRHAGIC PANCREATITIS HAS COME OF AGE. *(E.)* Geokas, M. C.; Rinderknecht, H. (Sepulveda VA Hosp., Los Angeles, Calif.). *Gastroenterology* 66(4):696, 1974.

4387 CALCIUM BINDING PROTEIN IN HUMAN DUODENAL BIOPSIES. *(E.)* Gleason, W. A.; Alpers, D. H. (Washington Univ. Sch. Med., St. Louis, Mo.). *Gastroenterology* 66(4):699, 1974.

4388 RADIOIMMUNOASSAY (RIA) OF CHOLECYSTOKININ-PANCREOZYMIN (CCK-PZ) IN HUMAN SERUM. *(E.)* Go, V. L. W.; Cataland, S.; Reilly, W. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 66(4):700, 1974.

4389 MEASUREMENT OF CHOLECYSTOKININ-PANCREOZYMIN LEVELS IN PERIPHERAL VENOUS BLOOD IN MAN. *(E.)* Harvey, R. F.; Mathur, M. S.; Dowsett, L.; Read, A. E. (Univ. Dept. Med., Bristol, England). *Gastroenterology* 66(4):707, 1974.

4390 ANGIOGRAPHY AND ANGIOPHARMACOLOGY IN GI BLEEDING - RESULTS AND PROBLEMS. *(E.)* Karmody, A. M.; Ballint, J. (Albany Med. Coll., N. Y.). *Gastroenterology* 66(4):720, 1974.

4391 FATE OF THE RECTAL STUMP IN ULCERATIVE COLITIS: EXFOLIATIVE CYTOLOGY AS AD-JUNCTIVE DIAGNOSTIC AID. *(E.)* Katz, S.; Katzka, I.; Schneider, K.; Silverberg, M. (North Shore Univ. Hosp., New York, N.Y.). *Gastroenterology* 66(4):721, 1974.

4392 EXFOLIATIVE COLONIC CYTOLOGY IN DIAGNOSING CANCER IN ULCERATIVE COLITIS. *(E.)* Katz, S.; Katzka, I.; Platt, N. (Long Island Jewish Hillside Med. Ctr., New Hyde Park, N.Y.). *Gastroenterology* 66(4):721, 1974.

4393 IMPAIRED BILE ACID CLEARANCE: A SENSITIVE INDICATOR OF LIVER DISEASE. *(E.)* Korman, M. G.; LaRusso, N. F.; Hoffman, N. E.; Hofmann, A. F. (Mayo Clin., Rochester Minn.). *Gastroenterology* 66(4):727, 1974.

4394 GASTRO-ESOPHAGEAL REFLUX: EVALUATION OF 9 DIAGNOSTIC CRITERIA. *(E.)* Krejs, G. J.; Seefeld, U.; Haemmerli, U. P.; Braendli, H. H.; Caro, G.; Bron, B. A.; Schmid, P.; Blum, A. L. (Triemli Munic. Hosp., Zurich, Switzerland). *Gastroenterology* 66(4):727, 1974.

4395 GLUCAGON DECREASES COLON SPASM AND PATIENT DISCOMFORT AND IMPROVES DIAGNOSTIC QUALITY OF BARIUM ENEMA. *(E.)* Meeroff, J. C.; Jorgens, J.; Isenberg, J. I. (Wadsworth Hosp. Ctr., Los Angeles, Calif.). *Gastroenterology* 66(4):744, 1974.

4396 EARLY DETECTION OF GASTROINTESTINAL CARCINOMA. *(E.)* Molnar, I. G.; Koretz, R. L.; Hunt, J. S.; Gitnick, G. L. (Univ. California, Los Angeles). *Gastroenterology* 66(4):748, 1974.

4397 A PROSPECTIVE RANDOMIZED STUDY OF DIAGNOSIS AND MANAGEMENT IN UPPER GASTROINTESTINAL (UGI) BLEEDING: ENDOSCOPY (E) VERSUS UGI SERIES (X). *(E.)* Morris, D. W.; Levine, G. M.; Soloway, R. D.; Miller, W. T.; Marin, G. A. (Univ. Pennsylvania Hosp., Philadelphia). *Gastroenterology* 66(4):751, 1974.

4398 QUANTITATIVE SERUM LIPOPROTEIN-X (LP-X) BEFORE AND AFTER CHOLESTYRAMINE (CSM) IN THE DIAGNOSIS OF EXTRAHEPATIC BILIARY ATRESIA (EBA). *(E.)* Poley, J. R.; Alaupovic, P.; Magnani, H. N.; Bhatia, M.; Smith, E. I.; Campbell, D. P. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Gastroenterology* 66(4):761, 1974.

4399 DIAGNOSTIC ACCURACY OF PANCREATIC ARTERIOGRAPHY: COMPARISON OF SELECTIVE AND SUPERSELECTIVE STUDIES. *(E.)* Rosch, J.; Holman, D. C.; Antonovic, R. (Univ. Oregon Med. Sch., Portland). *Gastroenterology* 66(4):768, 1974.

4400 STATISTICAL COMPARISON BY RANK TEST OF SIGMOIDOSCOPIC APPEARANCE AND HISTOLOGICAL ANALYSIS OF RECTAL BIOPSIES IN ULCERATIVE AND GRANULOMATOUS COLITIS. *(E.)* Sommers, S. C.; Korelitz, B. I. (Lenox Hill Hosp., New York, N.Y.). *Gastroenterology* 66(4):781, 1974.

4401 PROSPECTIVE EVALUATION OF CARCINOEMBRYONIC ANTIGEN AS A SCREENING TEST FOR CANCER. *(E.)* Stevens, D. P.; Mackay, I. R. (Walter and Eliza Hall Inst. Med. Res., Melbourne, Australia). *Gastroenterology* 66(4):783, 1974.

4402 EVALUATION OF RADIOGRAPHIC LUCENCY OR OPAQUENESS OF GALLSTONES AS A MEANS OF IDENTIFYING CHOLESTEROL OR PIGMENT STONES: CORRELATION OF RADIOPAQUENESS WITH MINERAL CONTENT. *(E.)* Trotman, B. W.; Petrella, E.; Soloway, R. D.; Sanchez, H.; Morris, T.; Miller, W. T. (Dept. Med., Univ. Pennsylvania, Philadelphia). *Gastroenterology* 66(4):791, 1974.

4403 CYTOLOGICAL, IMMUNOLOGICAL (CEA), AND ISOTOPE LABELING STUDIES BASED ON GASTROINTESTINAL ENDOSCOPIC LAVAGE. *(E.)* Winawer, S. J.; Fleisher, M.; Melamed, M.; Sherlock, P.; Deschner, E.; Schwartz, M. (Memorial Sloan-Kettering Cancer Ctr., New York, N.Y.). *Gastroenterology* 66(4):800, 1974.

GASTROINTESTINAL DISEASES

ESOPHAGUS

4468 SPECIFIC TUBERCULAR ESOPHAGITIS. *(Ger.)* Heuck, F. (Katharinen Hosp., Stuttgart, Germany). *Radiologe* 13(9):377-379, 1973.

Chest x-rays from an 87-yr-old man showed decreased esophageal peristalsis, irregular contours of the wall in the middle to caudal part of the esophagus, an irregularly shaped ulcer, and gastroesophageal reflux. A diagnosis of reflux esophagitis was established on the basis of these findings. In addition to senile emphysema, partially calcified lymph nodes were present in the pulmonary hili and poorly defined foci were observed in the upper left field. The patient died suddenly of heart and circulatory failure 2 weeks later. Autopsy showed the presence of old tubercular changes in the left upper lobe of the lung, granulation and ulceration of the caudal part of the esophagus, and yellowish or gray nodules with caseous necrotic masses in peripheral regions. Histological examination revealed tubercular changes with epitheloid cells, granulations, and an increase in scar tissue. No perforations were present. The absence of severe tubercular changes near the esophagus suggests that preexisting miliary tuberculosis had been reactivated. It is concluded that a differential diagnosis of inflammatory diseases of the esophagus cannot be established on radiological evidence alone. Esophagoscopy, histological examination of biopsies taken from different parts of the region involved, or the bacteriological detection of tuberculosis bacilli are needed for the diagnosis of tuberculous esophagitis.

4469 ESOPHAGEAL VARICES IN AGNOGENIC MYELOID METAPLASIA: DISAPPEARANCE AFTER SPLENECTOMY. A CASE REPORT. *(E.)* Sullivan, A.; Rheinlander, H.; Weintraub, L. R. (Univ. Hosp., Boston, Mass.). *Gastroenterology* 66(9):429-432, 1974.

A 65-yr-old man with massive splenomegaly secondary to agnogenic myelofibrosis and extramedullary myeloid metaplasia was found to have esophageal varices. No intra- or extrahepatic obstruction to portal blood flow was present. Splenectomy immediately reduced portal venous pressure from 34 to 19 cm of saline, and 2 months postoperatively no varices were demonstrable by barium swallow. Portal hypertension in certain cases of agnogenic myelofibrosis and extramedullary myeloid metaplasia may be mainly due to increased portal flow rather than increased resistance, and these individuals may benefit from splenectomy alone. In this patient polycythemia, leukocytosis, and thrombocythemia occurred post-splenectomy despite the extensive myelofibrosis noted at biopsy. This is compatible with the concept that myelofibrosis begins in the central bones of the body and is associated with initial conversion of the distal fatty marrow to panhyperplasia.

4470 EFFECT OF INTRAVENOUS METOCHLOPRAMIDE ON THE INCOMPETENT LOWER ESOPHAGEAL SPHINCTER. *(E.)* Guelrud, M. (Univ. Hosp., Caracas, Venezuela). *Am. J. Gastroenterol.* 61(2):119-124, 1974.

The effect of metoclopramide (10 mg i.v.) on the esophagus and lower esophageal sphincter pressure was studied manometrically in 23 patients: 12 without esophageal symptoms and without hiatus hernia and 11 with symptoms of gastroesophageal reflux and hiatus hernia. Metoclopramide increased the resting lower esophageal sphincter pressure in the reflux patients from a mean of 4.1 to 23.5 mm Hg. Metoclopramide also increased the amplitude and duration of pressure peristaltic waves in the lower esophagus. Atropine (0.5 mg i.v.) blocked this effect suggesting a final cholinergic pathway. It is concluded that metoclopramide would be a valuable addition to drug therapy for gastroesophageal reflux.

4471 THE SURGICAL TREATMENT OF REFLUX OESOPHAGITIS: RESULTS OF SURGICAL REPAIR OVER A 12-YEAR PERIOD. *(E.)* Wilson, M. G.; Bailey, I. S.; Penry, A. B. (Southmead Hosp., Bristol, England). *Br. J. Surg.* 61(3):193-200, 1974.

The results of surgical treatment of 81 cases of reflux esophagitis are reported. A simple repair (i.e., repair of the hiatus and reconstruction of the esophagogastric angle) was performed on 44 patients between 1958 and 1966, while 37 patients treated from 1966 to 1970 had fundoplications. About 1/2 the cases with simple repairs also had vagotomy and pyloroplasty, and some had cholecystectomy for associated gallstones. Comparing simple repair with fundoplication, 92% of the cases in both groups were good clinically, but radiologically 77% of the fundoplications were good compared with 60% of the simple repairs. Two of the simple repairs have required further surgery for recurrent esophagitis. There has been no recurrent esophagitis in the fundoplication group, but dysphagia has been a problem requiring reoperation in 1 case and repeated bouginage in 3 others. Postprandial discomfort due to difficulty in belching occurs. Vagotomy has not had a beneficial effect: the group without vagotomy was superior clinically and radiologically. Because of the complications of fundoplication, simple repair has been resumed with two modifications. The first is to improve the flap valve by attaching the fundus of the stomach to the whole anterior aspect of the abdominal esophagus. The second is to place a few stitches between the lesser curve of the stomach below the cardia and the preaortic fascia.

4472 HEALING OF CIRCULAR ESOPHAGEAL MUCOSAL DEFECTS: AN EXPERIMENTAL STUDY IN THE PIGLET. *(E.)* Kornfalt, S. A.; Okmian, L.; Jonsson, N. (Dept. Pediatr. Surg., Univ. Lund, Sweden). *Z. Kinderchir.* 13(2):184-197, 1973.

Circular mucosal defects were created in the esophagus of Swedish Landrace piglets (aged 2-3 weeks) by transection or excision of the mucosa. In one group of piglets with transected mucosa, an intraluminal tube was left in the esophagus running through the area of division. X-ray examinations, macrophotography, and microscopy revealed that mucosal defects invariably healed with complete occlusion of the lumen within 4 weeks. The predominant process in the stricture formation resembled wound contraction in full thickness wounds. Occlusion of the lumen could be prevented by an indwelling esophageal tube kept in place for more than 14 days; true regeneration of the epithelium and total cover of the mucosal defect was confirmed in all animals with tubes in place for 14-34 days. These findings support the importance of exact mucosal approximation in esophageal anastomoses. The use of a wide trans-anastomotic tube is recommended in cases where mucosal separation can be expected.

4473 THE INFLUENCE OF THE LOWER OESOPHAGEAL SPHINCTER PRESSURE ON THE OUTCOME OF HIATUS HERNIA REPAIR. *(E.)* Brennan, T. G.; Trindade, L. M.; Rozycki, Z. J.; Giles, G. R. (Leeds (St. James's Univ. Hosp., England). *Br. J. Surg.* 61(3):201-205, 1974.

Of 36 patients examined 6 months to 3 yr after simple repair of hiatus hernia, 12 (1/3) had persistent symptoms consisting of heartburn, reflux, dysphagia, vomiting, or dyspepsia. The symptoms were relatively mild in 4 cases and only 1 had severe symptoms due to gastroesophageal reflux. Persistence of symptoms could not be correlated with radiological reflux or reduced lower esophageal sphincter pressure. Radiological reflux was shown in 3 of 24 asymptomatic patients, while only 1 symptomatic patient had recurrent hernia. Sphincter resting pressures were below 10 mm Hg in 8 patients, all without reflux, including 4 asymptomatic patients.

4474 ESOPHAGEAL FUNCTION IN ELDERLY MEN: A NEW LOOK AT "PRESBYESOPHAGUS." *(E.)* Hollis, J. B.; Castell, D. O. (U.S. Naval Hosp., Philadelphia, Pa.). *Ann. Intern. Med.* 80(3):371-374, 1974.

Esophageal motility was studied in 21 nonhospitalized elderly men (aged 70-87 yr) and in 11 control subjects (aged 19-27 yr), all without neurological disease or diabetes. Esophageal function was studied basally and after administration of edrophonium chloride (80 µg/kg i.v.). For control subjects mean basal and postinjection amplitudes were significantly greater than those for aged subjects, with a marked decline in amplitude in subjects more than 80 yr old. In contrast to the decreased amplitude in 80-yr-old men, the propogation of peristaltic waves, as measured by speed, duration, and onset of contraction after a swallow, was similar for all groups and responded similarly to edrophonium chloride. No increase in abnormal spontaneous motility was noted in the elderly men. These findings suggest a weakening in esophageal smooth muscle with an intact nervous pathway. Disordered motility in elderly persons is most likely caused by disease, rather than by aging. It is suggested that presbyesophagus needs to be redefined.

4475 THE PROCESS OF DEGLUTITION WITH ACID BARIUM: A NEW KIND OF RADIOLOGICAL TEST IN PATIENTS WITH REFLUX DISORDERS. *(Ger.)* Donner, M. (Johns Hopkins Med. Inst., Baltimore, Md.). *Radiologe* 13(9):372-376, 1973.

A new radiological technique is described for the diagnosis of gastroesophageal reflux. While in a prone position and tilted 45° to the right, patients are given a neutral barium suspension (pH 6-7) to swallow. This is followed by an acid suspension of barium (pH 1.6-1.7), about 30 ml of an antacid, and a neutral barium suspension again. Of 278 patients with symptoms of gastroesophageal reflux, 236 (85%) developed spastic contractions of the esophagus lasting 20-30 sec after swallowing the acid barium suspension. Another 35 of these patients (12.6%) developed severe esophageal spasms after swallowing neutral barium suspensions. Only 7 of the 278 patients with symptoms of reflux failed to develop esophageal spasms after administration of barium suspensions. Gastroesophageal reflux was demonstrated in 169 of these 278 patients and 180 had hiatus hernia. Of 80 symptomatic patients, only 3 had positive tests with acid barium suspensions. Hiatus hernia was diagnosed in 14 of these 80 controls.

4476 USE OF METHOTREXATE AND TELEGAMMATHERAPY IN ESOPHAGEAL CANCER. *(Rus.)* Kusherbaev, S. K.; Dement'eva, N. I.; Zhangarashev, K. S.; Tsoi, A. I.; Balmukhanov, S. B. (no affil.). *Vopr. Onkol.* 20(4):23-28, 1974.

STOMACH

4494 STRESS INDUCED GASTRIC LESIONS IN SPONTANEOUSLY HYPERTENSIVE RATS: INVOLVEMENT OF AUTONOMIC NEUROTRANSMITTER SUBSTANCES. *(E.)* Goldenberg, M. M. (Norwich Pharmacal Co., N.Y.). *Am. J. Dig. Dis.* 19(4):353-360, 1974.

The roles of the parasympathetic and sympathetic nerves in the induction of gastric hemorrhagic lesions induced by cold-plus-restraint stress were studied in spontaneously hypertensive (SHR) rats. After bilateral vagotomy or reserpine treatment (1 mg/kg, i.p.), partial reduction in the incidence and severity (per stomach) of gastric lesions was observed. Vagotomy plus reserpine, levodopa, or levodopa plus reserpine significantly decreased the number and incidence of lesions. Nonhemorrhagic gastric ulcers developed in SHR after vagotomy or vagotomy plus reserpine. In normotensive Wistar rats, bilateral vagotomy and levodopa failed to affect stress-induced lesions. Reserpine increased the number of frequency of lesions, while vagotomy and levodopa abolished the responses to reserpine. Nonhemorrhagic gastric ulcers were not seen in normotensive rats. The data indicate that acetylcholine and norepinephrine, released from the parasympathetic and sympathetic nerves, respectively, play paramount roles in the induction of hemorrhagic gastric lesions by cold-plus-restrain stress in SHR.

4495 PREVENTION OF ANTIINFLAMMATORY DRUG-INDUCED GASTRIC LESIONS IN RATS BY ABBOTT-29590. *(E.)* Dodge, P. W.; Brodie, D. A.; Young, P. R.; Krause, R. A.; Tekeli, S. (Abbott Labs., Chicago, Ill.). *Am. J. Dig. Dis.* 19(5):449-457, 1974.

Abbott-29590[2,3-dihydro-1H-pyridino-(2,3-b)(1,4)-thiazine-2-one], an antiinflammatory compound with antipyretic and analgesic activity in test animals, did not produce any gastric lesions in the rat after p.o. administration of doses up to 256 mg/kg. In contrast, gastric lesions were produced by p.o. administration of aspirin, indomethacin, and phenylbutazone. The ED$_{95}$ values were 88, 13, and 260 mg/kg, resp. Pretreatment with Abbott-29590 prevented gastric damage induced by aspirin and indomethacin, but not ulceration induced by phenylbutazone. The ED$_{50}$ values of Abbott-29590 for preventing gastric lesions induced by aspirin, Abbott-29590, and exogenous 0.1 N HCl suggest that Abbott-29590 was additive with aspirin in its antiinflammatory activity and simultaneously blocked gastric lesions produced by aspirin. The antiinflammatory activity of indomethacin in the carrageenin rat paw edema test was not altered by 30 min pretreatment with Abbott-29590, while phenylbutazone and Abbott 29590 were additive in antiinflammatory activity. Studies of gastric lesions produced by a combination of aspirin, Abbott-29590, and exogenous 0.1 N HCl suggest that Abbott-29590 may tighten the gastric mucosal barrier.

4496 TOPOGRAPHY AND FINE STRUCTURE OF ACUTE FUNDIC MUCOSAL EROSIONS IN THE RAT. *(E.)*

Morris, G. P.; Harding, R. K. (Dept. Biol., Queen's Univ., Kingston, Canada). *Lab. Invest.* 30(5):639-646, 1974.

Acute focal mucosal lesions developed in rats after exposure to a response-avoidance schedule of 3-12 hr duration. The topography of the fundic mucosa of experimental, yoked control, and normal animals was compared in the scanning electron microscope. Transmission electron microscopy was employed to substantiate and clarify the results of these topographic studies. The luminal surfaces of normal surface epithelial cells are relatively flat, polygonal, and fit closely together. Occasionally, concentrations of shallow apical erosions were seen in normal animals. Apical swelling of surface epithelial cells was extensive in experimental animals, and apical erosions were more numerous, deeper, and less uniform in outline than in normal controls. This apical swelling was accompanied by changes in the intracellular distributions of mucous granules and by separation of lateral cell surfaces, except in the region of the junctional complex. Cells bordering mucosal lesions showed extensive lateral and basal erosion, although their luminal surfaces were often intact. It is suggested that, after an initial surface breakthrough involving a small number of cells, mucosal lesions increase in area, primarily by erosion of the more vulnerable lateral and basal cell surfaces.

4497 JAPANESE GASTRIC CANCER. POTENTIALLY CARCINOGENIC SILICATES (TALC) FROM RICE.

(E.) Matsudo, H.; Hodgkin, N. M.; Tanaka, A. (St. Joseph Med. Ctr., Burbank, Calif.). *Arch. Pathol.* 97(6):366-368, 1974.

Consumption of rice coated with asbestos-contaminated talc has been suggested as the cause of the high incidence of gastric cancer among Japanese. Formalin-fixed tumor tissue from 7 Japanese individuals with gastric cancer were processed for light and electron microscopy. Examination of the 7 gastric malignant neoplasms under the light microscope showed each to be a primary, fairly well-differentiated, infiltrating gastric adenocarcinoma, with varying degrees of mucous secretory activity, ulceration, desmoplasia and inflammation. Examination by polarized light of hematoxylin-eosin-stained slides revealed talc (10-36 μ in diameter) and crystalline spicules (0.8 x 6.4 μ to 4.0 x 16.0 μ) in only 1 of the 7 specimens. When examined with the transmission electron microscope, however, crystalline particles (about 0.5 μ or smaller) were observed in 6 of the 7 tumor specimens. Nothing was found in the other specimen. Scanning electron microscopy of a precipitate from rice wash water and washed rice disclosed identical crystals. Elemental x-ray analyses of these crystals showed that they were composed of magnesium and silicon and are probably talc. Since the magnesium silicate crystals of asbestos are definitely carcinogenic, the silicates found here should be considered potentially carcinogenic and the coating of rice with talc should be carefully reevaluated.

4498 PYLORIC INCOMPETENCE IN PATIENTS WITH SYMPTOMATIC GASTROESOPHAGEAL REFLUX.

(E.) Kaye, M. D.; Showalter, J. P. (Univ. Colorado Med. Ctr., Denver). *J. Lab. Clin. Med.* 83(2):198-206, 1974.

Duodenogastric regurgitation was measured in 10 patients with symptomatic gastroesophageal reflux and in 10 normal age- and sex-matched controls by serial determinations of the bile salt concentration in juice aspirated from the proximal portion of the stomach. Sliding hiatus hernias were radiologically diagnosed in 9 and distal esophageal stricture in 5. Esophagoscopy revealed manifest esophagitis with a friable mucosa and/or erosions in 7 of the 8 patients examined. The measurements were made over a 1-hr period under basal conditions and over a 4-hr period after ingestion of a standard liquid meal. The gastric bile salt concentrations were similar in the 2 groups of subjects under basal conditions, but after the meal they were consistently and significantly higher in the patients than in the controls. The peak bile salt concentrations in 6 of the patients exceeded the highest control value (0.89 + 0.24 compared with 0.21 + 0.05 mg/ml). The rate of decline in the gastric concentration of polyethylene glycol (included in the liquid meal) was similar in the 2 groups. These results indicate that regurgitation of the duodenal contents into the stomach is excessive in patients with symptomatic gastroesophageal reflux. One or more components of the postprandial duodenal juice may contribute to the development of esophagitis in patients with gastroesophageal reflux.

4499 EPIDEMIOLOGICAL INVESTIGATION ON STOMACH CANCER MORTALITY IN CHILEANS: ASSOCIATION WITH NITRATE FERTILIZER. *(E.)*

Zaldivar, R.; Robinson, H. (Univ. Tennessee Coll. Med., Memphis). *Z. Krebsforsch.* 80(4):289-295, 1973.

A multivariate statistical analysis was made of the relative contributions of exposure to fertilizer, rainfall and latitude to the variability of gastric cancer mortality rates in the Chilean Provinces. The method used was stepwise multiple regression. Results indicated that the major factor was exposure to sodium nitrate used as fertilizer. Associations between gastric cancer death rates on the one hand and proportions of farmers and farmer exposure to sodium nitrate on the other hand indicate that farmer deaths influenced the death rates by provinces. Of 1675 male workers in actual contact with the soil, farmers (31.2%) and miners (18.7%) accounted for 49.4% of all male deaths from stomach cancer.

4500 RADIOIMMUNOASSAY OF GROUP I PEPSINOGENS IN SERUM. *(E.)* Samloff, I. M.; Liebman, W. M. (Harbor Gen. Hosp., Torrance, Calif.). *Gastroenterology* 66(4):494-502, 1974.

A radioimmunoassay for the group I pepsinogens (PG I) in human serum has been developed. The standard PG I was isolated from human urine, and, when labeled with ^{125}I, was shown to be immunochemically homogeneous by radioimmunoelectrophoresis and radioimmunoprecipitation. The antiserum was obtained from rabbits immunized with partially purified PG I. Standard PG I and serum gave parallel inhibition curves against the labeled antigen. The sensitivity of the assay was on the order of 2 ng/ml serum. The reproducibility was demonstrated by the finding that of 15 pairs of determinations carried out 2 months apart, 13 differed from one another by less than 5% of the mean value. PG I in serum was stable for at least 7 months at -20 C. The mean serum PG I levels in 69 healthy control subjects and 71 hospitalized control patients were 102.7 ± 32.5 and 96.2 ± 41.9 ng/ml. In 14 patients with pernicious anemia and in 12 patients with total gastrectomy, the mean serum PG I values were 10.2 ± 6.4 and 3.8 ± 2.9 ng/ml, respectively. In five patients with Zollinger-Ellison syndrome, the mean level was 456.1 ± 187.3 ng/ml. These data suggest that the extremes of gastric secretory function, namely, pernicious anemia and Zollinger-Ellison syndrome, are characterized, resp., by low and high levels of serum group I pepsinogens.

4501 SMALL-INTESTINAL FUNCTION IN VITAMIN B_{12} DEFICIENCY. *(E.)* Lindenbaum, J.; Pezzimenti, J. F.; Shea, N. (Harlem Hosp. Ctr., New York, N.Y.). *Ann. Intern. Med.* 80(3):326-331, 1974.

Intestinal function was studied in 28 patients with untreated pernicious anemia and no clinically apparent intestinal disease. Xylose absorption was impaired in 29% of these patients; fat, in 9%; and vitamin B_{12} given i.m. with intrinsic factor, in 75%. Xylose malabsorption was more common in patients with severe hematologic depression; it was generally reversible within 2-3 weeks after institution of vitamin B_{12} therapy. In most patients absorption of radioactive cyanocobalamin returned to normal within 1-8 weeks. In 4 patients cyanocobalamin absorption remained subnormal after 4-41 months of vitamin repletion. In 2 of these patients a 5-day course of p.o. tetracycline rapidly reversed the vitamin B_{12} malabsorption. The remaining 2 patients had high titers of serum antibodies to intrinsic factor (1:128 and 1:512). Reversible impairment of intestinal absorptive capacity is commonly associated with vitamin B_{12} deficiency. Abnormalities shown in absorption tests done within 2 months of initiating therapy in patients with pernicious anemia do not necessarily reflect primary small-intestinal disease.

Peptic Ulcers

4523 GASTRIC MUCOSAL pH. *(E.)* Earlam, R. J. (London Hosp., England). *Br. J. Surg.* 61(3):185-188, 1974.

The intragastric mucosal pH was measured routinely during the course of esophageal manometry in 263 hospital patients. The mean pH of 117 male patients with duodenal ulceration was 1.3 ± 0.3. Seventeen patients with gastric ulceration had a mean pH of 1.7 ± 0.3, and 19 patients with hiatal herniation had a mean pH of 1.6 ± 0.4. The gastric ulcer patients had a lower mean pH than 8 patients with gastric carcinoma (2.3 ± 0.9). The lowest pH values among the duodenal patients were changed by truncal vagotomy (37 patients) to 1.3 ± 0.8 and by Polya partial gastrectomy (25 patients) to 3.2 ± 1.8. If a stomal ulcer was present after partial gastrectomy, the pH was 1.1; this changed to above 1.9 after vagotomy.

4524 HISTOLOGIC STUDY OF GASTRIC LESIONS IN FOOD-RESTRICTED RATS (38012). *(E.)*

Pintar, K.; Schulte, W. J.; Barboriak, J. J. (VA Ctr., Wood, Wisc.). *Proc. Soc. Exp. Biol. Med.* 145(4):1353-1358, 1974.

Sprague-Dawley rats limited to food intake of 1 hr/day and allowed to run in an activity wheel developed gastric lesions which, on histologic examination, resembled human stress ulcers. The lesions in the animals started as small mucosal hemorrhages and developed progressively to form ulcers in the gastric mucosa. These lesions appeared to be initiated by a localized capillary congestion developing close to the mucosal surface below the basement membrane and "venting" toward the lumen. Pooling of blood led to a slight rise of accumulated material beneath the basement membrane, giving the appearance of pinpoint hemorrhage. Rupture of the basement membrane was probably followed by deepening and widening of the erosion and gave the appearance of a larger confluent lesion. In contrast to stress ulcers in man, no fibrin was observed in any of the lesions which developed in these rats. Most of the lesions in these rats were acute in nature and showed no evidence of healing. Some of the lesions penetrated to the submucosal layers. No thrombi were observed in the mucosal vessels.

4525 EFFECT OF SELECTIVE AND PROXIMAL GASTRIC VAGOTOMY ON SERUM GASTRIN. *(E.)* Jaffe, B. M.; Clendinnen, B. G.; Clarke, R. J.; Williams, J. A. (Washington Univ. Sch. Med., St. Louis, Mo.). *Gastroenterology* 66(5):944-953, 1974.

Forty patients with uncomplicated duodenal ulcer were randomized for treatment by either proximal gastric or selective vagotomy. Only the last 20 patients (10 with selective and 10 with proximal gastric vagotomy) had an accompanying pyloroplasty. Both types of vagotomy had equivalent effects on gastric acid secretion, inhibiting basal output an average of 79% and insulin-evoked output an average of 95%. Final gastric emptying times, measured by double dye dilution, were significantly shortened in patients who were treated by proximal gastric vagotomy plus pyloroplasty and lengthened in the 10 patients who had selective vagotomy without pyloroplasty. For all 40 patients, preoperative basal gastrin levels, measured by radioimmunoassay averaged 79 pg/ml. Both insulin and meat extract stimulated gastrin release, increasing serum gastrin levels by 50 and 67%. After vagotomy, basal gastrin concentrations were increased 57% over the preoperative determinations. Vagotomy augmented the gastrin response to meat extract; the degree of augmentation was similar in patients treated by proximal gastric or by selective vagotomy. However, the performance of a pyloroplasty limited the increased responsiveness to feeding (+155% in patients with pyloroplasty and +483% in patients without pyloroplasty). The gastrin response to insulin hypoglycemia was maintained equally after both types of vagotomy and was unaffected by pyloroplasty. In 7 patients with incomplete selective vagotomy, insulin resulted in a gastrin increase averaging 102 pg/ml, whereas in patients with complete selective vagotomy the increase averaged only 46 pg/ml.

4526 UPPER GASTROINTESTINAL DISEASE IN RHEUMATOID ARTHRITIS. *(E.)* Sun, D. C. H.; Roth, S. F.; MITCHELL, C. S.; Englund, D. W. (VA Hosp., Phoenix, Ariz.). *Am. J. Dig. Dis.* 19(5):405-410, 1974

Upper gastrointestinal series were performed on 140 consecutive patients with rheumatoid arthritis, regardless of whether or not they had symptoms suggesting upper gastrointestinal disease. In addition, intraluminal pH and manometric studies of the esophagus and esophagoscopic examinations were done in 66 of these 140 patients. Gastric ulcers were found in 12 patients, and duodenal ulcers in 27, an incidence of peptic ulcer disease of 27.8%. The highest incidence of ulcers was found in patients on corticosteroids (40%) and in those on a combination of corticosteroids with indomethacin or phenylbutazone (43%). No ulcers occurred in patients receiving gold therapy. Among the 66 patients who had esophageal motility studies, a significantly lower mean amplitude of peristaltic contractions was noted in the lower 2/3 of the esophagus. The resting pressure in the lower esophageal sphincter was also significantly lower than in the control group. However, no correlation was found between these 2 parameters and the duration or stage of rheumatoid arthritis. It is impossible to determine whether the upper gastrointestinal dysfunction observed in these patients is another systemic manifestation of the rheumatoid disease or is caused by drugs.

4527 THE EFFECT OF LOCALLY ADMINISTERED PROSTAGLANDIN 15 (R) 15 METHYL-E$_2$ METHYL ESTER ON GASTRIC ULCER FORMATION IN THE SHAY RAT PREPARATION. *(E.)* Carter, D. C.; Ganesan, P. A.; Bhana, D.; Karim, S. M. M. (Dept. Surg., Makerere U., Kampala, Uganda). *Prostaglandins* 5(5):455-462, 1974.

The 21-hr pylorus-ligated (Shay) rat model was used to assess the ulcer-protecting activity of locally administered prostaglandin 15 (R) 15 methyl-E$_2$ ester. After pyloric ligation, 0-50 µg/kg of prostaglandin were injected into the gastric lumen of female Sprague-Dawley rats. Among untreated Shay rats none were ulcer-free and 3 died. In contrast, 8 of the 15 animals receiving 50 µg/kg of prostaglandin were ulcer-free and none died. The difference in the incidence of ulcers between these two groups is highly significant. Shay rats receiving 25 µg/kg of prostaglandin also had significantly fewer ulcers than the controls. There were 5 perforations in the control group as compared with 1 perforation in each of the 3 treatment groups. Ulcers of the esophagus and glandular stomach were more common in the controls and Shay rats given 12.5 µg/kg of prostaglandin than in the animals given larger doses of prostaglandin. The weight-related acid content (mEq/kg) of the stomach at sacrifice was inversely related to the prostaglandin dosage although the mean acid content in the animals treated with 12.5 µg/kg of prostaglandin did not differ from that of the controls. The ulcer-protecting effects of locally administered prostaglandin

15 (R) 15 methyl-E$_2$ ester appear to be due to an initial inhibition of the gastric secretion induced by pyloric ligation. Consequently exposure of the gastric mucosa to unbuffered gastric juice is reduced. Although the exact mode of action of the analog is unknown, the evidence suggests direct inhibition of the gastric secretory cells.

4528 THE COEXISTENCE OF DUODENAL ULCER AND GASTRIC CARCINOMA. *(E.)* Hardy, K. J.; Grossberg, P. (Repatriation Gen. Hosp., Heidelberg, Australia). *Aust. N.Z. J. Surg.* 43(3):235-238, 1973.

Case reports are presented for 4 patients (4 men aged 32-78 yr) with coexisting gastric carcinoma and duodenal ulcer. In two cases, the duodenal ulcer had been present for more than 12 years. In the other 2 cases, the history of ulcer was short and involved weight loss, vague pain, and hematemesis. Each patient was in blood group A. Surgical treatment consisted of resection in three cases and bypass in the fourth. Two of the 4 patients developed liver metastases and died within 3 months. Since the diagnosis of gastric carcinoma is difficult in patients with duodenal ulcer, early endoscopy and exfoliative cytological examination are recommended for duodenal ulcer patients who are in blood group A, are elderly, or who have an atypical history. The prognosis of gastric carcinoma associated with duodenal ulcer is better than that of gastric carcinoma alone.

4529 GASTRIC SECRETION IN PYLORUS-PRESERVING GASTRECTOMY IN DOGS. *(E.)* Sugawara, K.; Isaza, J.; Woodward, E. R.; Eisenberg, M. M. (Univ. Florida Coll. Med., Gainesville). *Am. J. Surg.* 127(3):244-247, 1974.

The effects of pylorus-preserving gastrectomy on gastric secretory output were studied in parasympathetically denervated Heidenhain pouch dogs. After the operation, the volume decreased 75.9%; the free acid output decreased, 83.7%; the acid concentration decreased, 32.4%. Volume, free acid output, and acid concentration decreased slightly further after total antrectomy. Diminution of acid secretory rate is achievable, therefore, without sacrifice of pyloric sphincteric mechanism.

4530 SERUM GASTRIN AND GASTRIC ACID SECRETION BEFORE AND AFTER PROXIMAL GASTRIC VAGOTOMY. *(E.)* Schrumpf, E.; Roland, M.; Liavag, I. (Ulleval Univ. Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 9(2):115-118, 1974.

Serial determinations of the fasting serum gastrin concentrations and gastric acid secretion were performed on 8 patients with duodenal ulcer before and 3-12 months after proximal gastric vagotomy. The basal acid output and acid output after stimulation with pentagastrin (6 μg/kg s. c.) were reduced by a mean of 80% and 59%, resp. 3 months after vagotomy. A concomitant increase occurred in the mean basal gastric pH (from 1.9 ± 0.2 to 5.0 ±0.9), and the mean fasting serum gastrin concentration increased significantly. Between 3 and 12 months after proximal gastric vagotomy a moderate increase occurred in the residual gastric volume, along with a slight decrease in the basal gastric pH and the fasting serum gastrin concentration. These changes were not significant. The pH of the gastric juice appears to be the most important factor controlling fasting serum gastrin levels in patients with duodenal ulcer.

4531 EFFECT OF PROSTAGLANDIN 15 (R) 15 METHYL-E$_2$ ESTER ON THE GASTRIC MUCOSA IN PATIENTS WITH PEPTIC ULCERATION: AN ENDOSCOPIC AND HISTOLOGICAL STUDY. *(E.)* Fung, W. P.; Lee, S. K.; Karim, S. M. M. (Dept. Med., Univ. Singapore). *Prostaglandins* 5(5):465-472, 1974.

A single dose of prostaglandin 15 (R) 15 methyl-E$_2$ ester (150 μg) was administered p.o. *via* duodenofiberscope into the stomachs of 8 male Chinese patients with peptic ulcers. Gastric biopsy specimens obtained before and after prostaglandin treatment were examined endoscopically and histologically. The initial endoscopic diagnosis was acute gastritis in 6 cases, gastric ulcer in 1 case, and antral scarring with gastritis in 1 case. In 2 cases there was no significant change 1 hr after prostaglandin treatment. However, in the remaining 6 cases a marked increase occurred in viscid mucous secretion over the gastric mucosa. In 2 of these cases, the mucous secretion appeared to be "foamy". Prostaglandin also produced changes in the mucus-secreting cells in all 8 patients; mucus had accumulated in markedly increased amounts in these cells, causing peripheral displacement of their nuclei and luminal bulging of their walls. No appreciable changes occurred in the type or number of inflammatory cells or in the appearance of the parietal or chief cells. Since mucus is a natural protective material for the gastric mucosa, increased amounts of this substance might be beneficial in the healing of gastric ulceration.

4532 ASPIRIN USE IN PATIENTS WITH MAJOR UPPER GASTROINTESTINAL BLEEDING AND PEPTIC-ULCER DISEASE: A REPORT FROM THE BOSTON COLLABORATIVF DRUG SURVEILLANCE PROGRAM, BOSTON UNIVERSITY MEDICAL CENTER. *(E.)* Levy, M. (Boston Collaborative Drug Surveillance Program, Waltham, Mass.). *N. Engl. J. Med.* 290(21):1158-1162, 1974.

Possible relations between long-term regular use of aspirin-containing drugs and hospital admissions for (1) major upper gastrointestinal bleeding in the absence of known predisposing conditions and (2) newly diagnosed peptic ulcers were explored in a large hospital survey. For patients admitted with major bleeding and in whom there was no evidence of duodenal ulcer, there was a statistically significant association with aspirin taken regularly for 4 or more days/week. A similar association was found for patients admitted with newly diagnosed and uncomplicated benign gastric ulcer. The corresponding estimated incidence rates of hospital admissions for these two conditions attributable to heavy aspirin use were 15 and 10/100,000 users/yr, resp. Aspirin taken regularly for 4 or more days/week was not significantly associated with either bleeding or uncomplicated duodenal ulcer. There was no evidence of an association between light aspirin use (1-3 days/week) and the diseases under consideration.

4533 THE EFFECT OF VAGOTOMY AND DRAINAGE ON THE SMALL BOWEL FLORA. *(E.)* Browning, G. G.; Buchan, K. A.; Mackay, C. (Western Infirm., Glasgow, Scotland). *Gut* 15(2):139-142, 1974.

The incidence of bacterial colonization of the upper small intestine was assessed in 35 patients with chronic duodenal ulcer and 25 patients who had undergone elective surgery for chronic duodenal ulcer. The incidence of colonization of the upper small intestine in the unoperated patients was 3%, while in the first 7 to 10 days following vagotomy and drainage, 92% of the operated patients were colonized. None of 8 patients with a simple closure of a perforated ulcer was colonized. Thirty-two percent of the operated patients remained colonized 18 months postoperatively. The type of drainage procedure (Heinecke-Mikulicz pyloroplasty or retrocolic gastrojejunestomy) did not affect the incidence of colonization immediately after surgery. However, the incidence of colonization at follow-up was significantly lower among those subjected to pyloroplasty than among those subjected to gastrojejunostomy. The maximal acid output did not differ among those who were colonized and those who were not colonized, either immediately after or 18 months after surgery. Only two patients developed episodic diarrhea and there was no obvious association with bowel colonization. The presence of a potential blind loop among the gastrojejunostomy patients may explain the comparatively high incidence of bowel colonization among this group as compared with the pyloroplasty group.

4534 MECHANISM OF STRESS ULCER. II. DIFFERENCES BETWEEN THE ANTRUM, CORPUS, AND FUNDUS WITH RESPECT TO THE EFFECTS OF COMPLETE ISCHEMIA ON GASTRIC MUCOSAL ENERGY METABOLISM. *(E.)* Menguy, R.; Masters, Y. F. (Univ. Rochester Sch. Med. Dent., N.Y.). *Gastroenterology* 66(4):509-516, 1974.

It has been suggested that the event linking hemorrhagic shock-induced gastric mucosal ischemia and "stress ulceration" may be a rapid and profound decrease in gastric mucosal energy metabolism. To test this hypothesis, male Holtzman rats and male albino rabbits were given a 5% nutrient solution of sucrose containing a salt mixture. The next morning during laparotomy, a ligature was placed around the esophagus immediately above the stomach. At a given moment, the stomach was removed. In the rats and rabbits, the levels of ATP as well as those of (ATP + ADP + AMP) were significantly higher in the mucosa of the corpus than in the antrum. In addition, the rate of dephosphorylation was significantly greater in the mucosa of the corpus than in the antral mucosa. In rabbits, the ADP and AMP levels were significantly lower in the antral mucosa than in the corpus. In the fundus, the ATP levels were lower than in the corpus. The level of glucose-6-phosphate in the antral mucosa was lower than in the corpus or fundus. Although the energy deficit was slightly more severe in the fundus than in the corpus, this difference was not significant. Thus, the antrum is better able to sustain its energy metabolism in the face of ischemia, lending support to the original hypothesis linking stress ulceration with hemorrhagic shock-induced gastric mucosal ischemia.

SMALL INTESTINE

4550 ASSOCIATED MIDGUT MALROTATION AND MECKEL'S DIVERTICULUM PRESENTING IN ADULT LIFE. *(E.)* Harvey, J. S.; Giles, G. R. (Leeds Univ. Hosp., England). *Br. J. Surg.* 61(2):157-158, 1974.

Two case reports are presented of adult patients who presented with abdominal colic and were found to have malrotation of the midgut. The first patient was 47 years old, the second was 17. The first patient gave a history of attacks of central abdominal pain and vomiting for over 7 years. The present attack had lasted for 8 hours at the time of admission, was a colicky periumbilical pain which did not radiate and was without associated symptoms. A barium enema examination revealed the colon to be situated entirely on the left of the abdomen and a barium meal and follow-through examination showed that the small bowel was mainly on the right side of the abdominal cavity. A laparotomy was performed through a midline incision, confirming a complete failure of rotation of the midgut. The caecum was in the left lower quadrant of the abdomen with the remaining colon looped up into the left hypochondrium. The palpable abdominal mass was due to a large Meckel's diverticulum which was attached by its tip to the umbilicus. The affected ileum and caecum were excised together with the Meckel's diverticulum and an end-to-end anastomosis was constructed. The second patient was complaining of a colicky central abdominal pain which had been present for 20 hours, during which time he had vomited twice with some relief of the pain. Four months later, barium studies confirmed the diagnosis of intestinal malrotation. At laparotomy the caecum was found in the left hypochondrium with complete nonrotation of the midgut. The ileum was obstructed by a loop of small bowel passing through a tunnel produced by a long Meckel's diverticulum which had folded on itself and stuck to the base of the mesentery.

4551 SURGICAL TREATMENT OF ABDOMINAL ANGINA: REVIEW OF 25 PATIENTS. *(E.)* Reul, Jr., G. J.; Wukasch, D. C.; Sandiford, F. M.; Chiarillo, L.; Hallman, G. L.; Cooley, D. A. (Texas Heart Inst., Houston). *Surgery* 75(5):682-689, 1974.

Over a period of 9 yr, 25 patients between the ages of 19 and 72 yr underwent mesenteric revascularization for symptoms of abdominal angina, a rare condition resembling the angina pectoris which is associated with coronary artery disease. In most cases, postprandial abdominal pain and loss of weight combined with arteriographic findings of occlusive lesions of at least two of the three major visceral arteries (celiac, superior mesenteric, inferior mesenteric) established the diagnosis. Simultaneous surgical correction of an associated vascular or gastrointestinal disease was performed in 14 of the patients. Concomitant lesions which were also treated included abdominal aortic aneurysm in 5 patients, renal artery hypertension in 3, and aortoiliac occlusive disease in 3. Among these 25 patients, 38 arteries were revascularized. Two patients died, both deaths resulting from mesenteric infarction following unsuccessful revascularization procedures. Nine of the 18 remaining patients were doing quite well at follow-up examinations 5 months to 8 yr later. Successful operative treatment of abdominal angina depends upon accurate preoperative diagnosis based on evaluation of the symptoms and correlation with anatomical disease.

4552 MASSIVE GASTROINTESTINAL HEMORRHAGE FROM DUODENAL DIVERTICULA.

(E.) Lapin, R.; Kamath, M. L.; Engler, J.; Friedman, H. (no affil.). *Am. J. Gastroenterol.* 61(3):185-189, 1974.

A case report is presented for a 67-yr-old man with an ulcer in the diverticulum that was diagnosed before surgery by radiological work. The patient had no evidence of chronic liver disease. At gastroscopy, performed 3 hr after admission, no lesions could be identified in the stomach or the pylorus, but blood was refluxing from the duodenum. An upper gastrointestinal series revealed a rather large diverticulum in the third portion of the duodenum without any other associated lesion. The patient's condition stabilized after transfusion of 3500 ml blood, but a decision for surgical intervention was reached 5 days after admission when the patient exhibited a drop in the hematocrit associated with melena. At operation, a duodenogastrotomy failed to reveal the source of bleeding and was closed as a pyloroplasty. After mobilization of the duodenum the diverticulum, measuring 4 1/2 cm x 2 cm, was freed posteriorly from the surrounding pancreatic tissue and, after an anterior duodenotomy was performed, the sac was inverted and excised at its neck. The diverticulum was filled with fresh clots, and the mucosa showed numerous superficial ulcerations and erosions. It is concluded that the increased use of selective angiography in the diagnosis of active gastrointestinal hemorrhage will help in more accurate preoperative localization of the bleeding site, especially in patients who have had more than one episode of bleeding and have no other significant lesion except for a duodenal diverticulum upon upper gastrointestinal x-ray examination. However, arteriography could not be performed on this patient because of technical difficulties.

4553 ACUTE AND CHRONIC MAGNESIUM DEFICIENCY FOLLOWING EXTENSIVE SMALL GUT RESECTION.

(E.) Nielsen, J. A.; Thaysen, E. H. (Aalborg Hosp. North, Denmark). *Abdominal Surg.* 16(4):87-89, 1974.

A 56-yr-old woman underwent emergency surgery for extensive resection of the small intestine because of occlusion of the superior mesenteric artery. Soon after surgery she developed the clinical manifestations of magnesium deficiency (diarrhea, mental blurring, twitchings, muscular weakness), and, after several weeks, this diagnosis was confirmed by the finding of a severely depressed serum concentration of this ion (0.8 mEq/l). The patient recovered within a few days following the i.v. administration of magnesium. Later, the treatment was supplemented with 1 g/day of potassium chloride. After 2 yr, the administration of magnesium was discontinued for 3 weeks. During the 3rd week there was a significant decline in the serum concentrations of magnesium and potassium (which was still being given); serum calcium remained virtually unchanged. The diagnosis of magnesium depletion depends upon the clinical features and measurements of magnesium in the serum and urine. Magnesium deficiency results in increased amounts of sodium and potassium salts being retained in the gut, where they may act as saline cathartics. The neuromuscular and mental disturbances of magnesium depletion are probably secondary to the hypocalcemia and to the defective transport of ions across cellular membranes. In the acute and severe magnesium deficiency syndrome, 60-100 mEq of this ion should be administered i.v. daily; long term supplementation can usually be given p.o.

4554 THE "HIDE-BOUND" SMALL BOWEL OF SCLERODERMA: CHARACTERISTIC MUCOSAL FOLD PATTERN.

(E.) Horowitz, A. L.; Meyers, M. A. (New York Hosp.-Cornell Univ. Med. Ctr., New York, N.Y.). *Am. J. Roentgens Radium Ther. Nucl. Med.* 119(2):332-334, 1973.

Small bowel series for 18 patients with scleroderma were reviewed. Eleven (61%) showed a strikingly narrowed intervalvular distance that was most marked in the jejunum and proximal ileum. Although almost invariably dilated, the duodenum did not consistently display this altered mucosal fold pattern. Sharp angulation of dilated jejunal loops with retracted folds was also noted. When barium fully opacified the dilated loops, the decreased intervalvular distance was manifested as a series of sharp "spines" projecting from the margin of the lumen. The valvulae themselves were not widened or blunted and maintained their normal axis perpendicular to the bowel lumen. No nodularity or "thumbprint" type defects were noted. Transient, nonobstructive intussusceptions occurred in 3 of the cases (17%). It is suggested that the narrowed intervalvular distances and the intussceptions are due to significant replacement of the longitudinal fibers in the muscularis propria with collagen. This condition in the small bowel is analogus to the changes that occur in the soft tissues of the hands and face, in which replacement of normal tissue by excess fibrosis creates a "hide-bound" appearance.

4555 CHANGE OF BILE ACID METABOLISM AND ABSORPTION OF VITAMIN B_{12} AFTER INTESTINAL SHUNT OPERATION IN OBESITY: A COMPARISON OF THREE TYPES OF OPERATION.

(E.) Dano, P.; Lenz, K. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):159-165, 1974.

An intestinal shunt operation for obesity was made in 33 patients. The following 3 types of operation were compared: Type I: 36 cm of proximal jejunum anastomosed end-to-side to 12 cm terminal ileum; Type II: 24 cm jejunum plus 24 cm ileum; Type III: 12 cm jejunum plus 36 cm ileum. After operation, there was a statistically significant increase of the glycine-taurine ratio in jejunal contents and of the transfer of glycine conjugates to the colon (abnormal breath test). There was a significant decrease of the bile acid concentration in the jejunum and of the absorption of vitamin B_{12}. The results in Type III-operated patients deviated significantly less from normal values for abnormal breath test and diminished vitamin B_{12} absorption than the results in patients with Type I or II operations. The study favors the choice of a Type III operation which preserves the longest segment of terminal ileum.

4556 EFFECT OF THREE TYPES OF INTESTINAL SHUNT OPERATION ON GASTRIC SECRETION IN OBESITY. *(E.)* Dano, P.; Vagn Nielsen, O. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):167-171, 1974.

In a prospective study, gastric secretion was studied before and after 3 types of intestinal shunt operation for obesity. In each type, 48 cm of functioning small intestine was preserved, but the ratio between functioning jejunum and functioning ileum was different. A slight but significant basal hypersecretion was found in patients with 24 cm or less of functioning jejunum. Peak acid output following pentagastrin stimulation was unchanged. None of the patients developed symptoms of peptic ulcer. In patients with a massive small bowel bypass, gastric hypersecretion could be due to deprivation of an inhibitor substance as well as liberation of a gastric secretagogue. By preserving a different ratio of jejunum and ileum in function, the greater role of the proximal jejunum control of the gastric secretion was confirmed.

4557 WEIGHT LOSS IN RELATION TO THE LENGTH OF SMALL INTESTINE LEFT IN CONTINUITY AFTER JEJUNOILEAL SHUNT OPERATION FOR OBESITY. *(E.)* Juhl, E.; Quaade, F.; Baden, H. (Bispebjerg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):219-221, 1974.

In 10 obese patients treated with jejunoileal anastomosis leaving 50 cm of functioning small bowel (37 cm proximal jejunum anastomosed end-to-side to 13 cm of distal ileum), the absolute weight loss was approximately the same irrespective of the patient's initial weight. The average decrease was 17 kg after 3 months, 27 kg after 6 months, and 36 kg after 18 months. This means that the very obese individuals stabilized their weights at a too high level. As the weight loss proved to be unrelated to degree and duration of reflux to the excluded ileum, the functioning small bowel was shortened in the next 5 patients to 47 cm (34 cm of proximal jejunum and 13 cm of distal ileum), whereupon the weight losses were greater after 3 months (23 kg), 6 months (38 kg), and 18 months (61 kg). The results indicate that the length of functioning small intestine is the main factor determining weight loss. The operation should be individualized in accordance with the initial body weight.

SMALL INTESTINE

Malabsorption

4576 EVALUATION OF A NEW FEEDING FORMULA FOR SUGAR MALABSORPTION. *(E.)* Walker-Smith, J.; Paterson, H.; Keating, S. (St. Bartholomew's Hosp., London, England). *Med. J. Aust.* 21(3):107-110, 1973.

Experience with a new versatile feeding formula for use in children with sugar malabsorption is reported. The formula CF_1 is a milk-based formula made from a medium calcium coprecipitate, which contains approximately 95% of the protein present in whole milk. In the preparation, the principal whey allergens, bovine serum albumin, and beta-lacto-globulin, are either denatured or omitted. The formula may be used as CF_1 plus 7.7% glucose initially, for children with lactose or sucrose, disaccharide, malabsorption. It can also be used as CF_1 plus 7.7% fructose in children with glucose malabsorption unaccompanied by fructose malabsorption. CF_1 may be used as a completely carbohydrate free formula for a short period and then with increasing increments of carbohydrate in infants with monosaccharide malabsorption. Of 39 children given this formula, 18 had sugar malabsorption as a complication of gastroenteritis. 8 had miscellaneous primary medical disorders with which sugar malabsorption is associated; and 12 had developed malabsorption after operation in the neonatal period. In 10 of 20 children who were given CF_1 with added carbohydrate, the clinical response to commencement of this feeding formula was rapid and effective with disappearance of diarrhea and rapid weight gain. Nineteen children were given CF_1 initially as a carbohydrate-free formula, and then increasing amounts of carbohydrate were added. In 4 children the weight gain was excellent, and in 12 the initial weight gain was slow, but was later satisfactory. Complications included hypoglycemia and hypokalemia. It is concluded that this feeding formula may well serve infants with massive small intestinal resection while they are intolerant to carbohydrates, but as their intolerance to carbohydrate diminishes they can then be given progressively larger amounts of carbohydrates.

4577 LATENT CELIAC SPRUE. *(E.)* Weinstein, W. M. (Dept. Med., Alberta, Edmonton, Canada). *Gastroenterology* 66(4):489-493, 1974.

The relation between dermatitis herpetiformis along with morphologically normal small intestinal mucosa and latent celiac sprue is presented. Two patients with dermatitis herpetiformis and one normal volunteer, all of whom had morphologically normal small intestinal mucosa, were placed on a high gluten diet for 22 to 30 weeks. Moderately abnormal and severe "flat" mucosal lesions were induced in both patients with dermatitis herpetiformis, but not in the normal volunteer. Neither patient with dermatitis herpetiformis developed clinical or laboratory evidence of malabsorption. On completion of the high gluten diet, 1 patient with dermatitis herpetiformis was studied on a normal gluten-containing diet, and his intestinal mucosa reverted toward normal by 16 weeks. Latent celiac sprue may be defined as a condition in which the intestinal mucosa becomes unequivocally abnormal in response to increased dietary gluten.

4578 MALABSORPTION SECONDARY TO MESENTERIC ISCHEMIA. *(E.)* Meyers, M. A.; Kaplowitz, N.; Bloom, A. A. (New York Hosp.-Cornell Univ. Med. Ctr., N.Y.). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):352-358, 1973.

A 62-yr-old man was hospitalized with a history of diarrhea and a 70 pound weight loss over a 15 month period. The clinical impression of malabsorption was confirmed by a radioactive triolein study demonstrating excretion of 50.5% of the administered dose of labeled fat in a pooled 72-hr stool specimen (normal is less than 5%). Less than 6.6% of the administered ^{131}I label appeared in the urine within 24 hours. An upper gastrointestinal and small bowel series, utilizing a colloidal barium suspension, demonstrated a sprue-like pattern, characterized principally by dilated jejunal loops, segmentation, and a transient ileal intussusception. On the 12th hospital day, the patient died after developing severe generalized abdominal pain and an abdominal bruit. At autopsy, there was infarction of the intestine extending from 1 cm distal to the ligament of Trietz to the rectosigmoid junction with a 0.5 cm perforation of the midjejunum secondary to infarct necrosis. In the ileum there was evidence of marked mucosal atrophy and submucosal fibrosis antedating the final episode. Three thrombi were found in the common celiacomesenteric trunk. A prepyloric ulcer of the greater curvature of the stomach had perforated, producing acute peritonitis. Acute centrolobular necrosis of the liver was also observed. It is concluded that a small bowel series demonstrating the features of mild dilatation of proximal jejunal loops with stasis, in the absence of hypersecretion and significant segmentation, is helpful in the differentiation of ischemic malabsorption from idiopathic sprue.

4579 ROUTE OF PROTEIN LOSS DURING A MODEL PROTEIN-LOSING GASTROPATHY IN DOGS. *(E.)* Munro, D. R. (Dept. Physiol., Univ. Michigan, Ann Arbor). *Gastroenterology* 66(5):960-972, 1974.

A protein-losing gastropathy was induced in mongrel dogs by irrigating their stomachs with dithiothreitol. Successful production of protein-losing gastropathy was diagnosed by leakage of Evans blue into the gastric contents after it had been injected into the left femoral vein. Horseradish peroxidase and Evans blue were injected into the left gastroepiploic artery in dogs without pouches to trace the route of vascular protein loss into the stomach lumen. Dithiothreitol consistently induced protein-losing gastropathy. Microscopically the damage consisted of dilation of the intercellular space and vacuole formation in a few surface mucous cells. In controls injected with peroxidase, the dense reaction product was always found in mucosal capillaries, but only rarely in small, restricted areas of the lamina propria. In dithiothreitol-treated dogs the peroxidase reaction product was consistently detected in the blood vessels, the lamina propria, the dilated and normal undilated intercellular space, and the gastric lumen. It is concluded that most protein loss occurs by an intercellular route in this acute protein-losing gastropathy.

4580 HISTOCHEMICAL STUDY OF JEJUNAL MUCOSA IN IDIOPATHIC TROPICAL MALABSORPTION SYNDROME. *(E.)* Tandon, B. N.; Bose, S. L. (All-India Inst. Med. Sci., New Delhi). *Indian J. Med. Res.* 62(1):93-98, 1974.

A histochemical study was made of jejunal biopsies from 18 patients (6 females and 12 males, aged 16-50 yr) with idiopathic tropical malabsorption syndrome. All but one patient had bowel disturbances, characterized by increased frequency of motion with passage of unformed semisolid or watery feces. Seventeen patients had lost from 2 to 7 kg in 6 months to 3 yr, and 11 patients had varying degrees of anemia. D-xylose absorption was abnormal in 15 cases, steatorrhea was present in 11 cases, and vitamin B_{12} malabsorption was diagnosed in 7 of the 15 patients on whom the Schilling test was performed. Jejunal histology was abnormal in 11 and normal in 7 patients. Alkaline phosphatase, the brush border marker enzyme was normal in 13, slightly decreased in 1 and markedly reduced in 1. Mitochondrial marker enzyme succinic dehydrogenase was markedly reduced in 17 cases and normal in only 1 patient. All the 7 patients with normal jejunal histology had decreased succinic dehydrogenase activities. Thus, mitochondrial injury, as indicated by reduced activity of the marker enzyme, succinic dehydrogenase, is an important feature in patients with idiopathic tropical malabsorption syndrome. Since mitochondria are the site of oxidative metabolism of the enterocyte, the absorptive and oxidative function of the cells fails due to mitochondrial injury. The finding of apparently well preserved brush border marker enzyme would suggest that the damage to the microvilli and the fuzzy coat is not an early or an important event in the organelle pathology of idiopathic tropical malabsorption syndrome. Thus, reduction in the surface area for absorption, due to damage of microvilli may not be as important in the pathophysiology of malabsorption in patients with idiopathic tropical malabsorption syndrome as biochemical derangements resulting from mitochondrial injury.

4581 INTESTINAL COCCIDIOSIS IN A PATIENT WITH ALPHA-CHAIN DISEASE. *(E.)* Henry, K.; Bird, R. G.; Doe, W. F. (Roy. Postgrad. Med. Sch., Hammersmith Hosp., London, England). *Br. Med. J.* 1(5907):542-543, 1974.

During an ultrastructural study of small-intestinal mucosa from a 23-yr-old Sardinian man suffering from α-chain disease, coccidia were identified within the absorptive and crypt epithelial cytoplasm immediately above the basement membrane. Although the intestinal coccidiosis in this case may be nothing more than a superimposed infection in an immunologically defective patient and may not play any etiological role in the pathogenesis of α-chain disease, this finding may be significant and warrants further investigation.

4582 ACTION OF 1α-HYDROXY VITAMIN D_3 ON CALCIUM ABSORPTION AND BONE RESORPTION IN MAN. *(E.)* Peacock, M.; Gallagher, J. C.; Nordin, B. E. C. (Gen. Infirm., Leeds, England). *Lancet* 1(7854):385-389, 1974.

Synthetic 1-α-hydroxy vitamin D_3 (1-α-hydroxycholecalciferol) was given p.o. in a dose of 25 μg/day to groups of patients in whom calcium malabsorption was a recognized feature. The patients responded with an increase in plasma calcium and phosphate and in calcium absorption irrespective of their pretreatment values. Net calcium resorption from bone was increased in all patients with normal renal function. In patients with renal failure, however, net bone resorption tended to decrease. The onset of action was rapid and could be seen within 24 hr. When administration of the vitamin was discontinued, the effects were not maintained and their disappearance depended on the duration of treatment. The vitamin is very potent in man and will be useful in treatment of patients with calcium malabsorption. The malabsorption of calcium in elderly people is not due to failure of the absorptive mechanism in the small bowel since these patients respond to the vitamin. However, the dose should be less than 25 μg/day to avoid excessive bone resorption and hypercalcemia.

4583 A FAMILY WITH PROTEIN-LOSING ENTEROPATHY. *(E.)* Shani, M.; Theodor, E.; Frand, M.; Goldman, B. (Chaim Sheba Med. Ctr., Tel Hashomer, Israel). *Gastroenterology* 66(3):433-445, 1974.

Eight of 28 children in 2 sibships resulting from consanguineous matings of first cousins once removed were affected by various combinations of edema, growth retardation, diarrhea, abdominal pain, and/or clubbing. Four of the patients died after they developed ascites. Autopsies on two of these cases revealed hepatic vein stenosis resulting in a Budd-Chiari syndrome. Laboratory examinations showed all affected family members had iron-deficiency anemia and low serum albumin and globulin; in some cases, mild eosinophilia was present. All patients had normal WBC. Five patients were investigated in detail, and a protein-losing enteropathy was revealed in all cases. In some patients, the intestinal biopsy showed slight to marked dilation of the mucosal lymphatics. Lymphangiography was normal in all 5 patients, and 3 formed antibodies in response to immunization with TAB vaccine. Administration of prednisone to 3 patients resulted in the disappearance of abdominal pain and edema in 2 cases, and the patients gained a considerable amount of weight. Serum protein levels returned to normal in all 3 prednisone-treated patients, their polyvinylpyrrolidone excretion decreased, and the parameters of protein metabolism returned to normal in the 1 patient in which they were reinvestigated. The cause of this familial protein-losing enteropathy is unknown, but it appears to be transmitted by an autosomal recessive mechanism.

4584 INTESTINAL MALABSORPTION: FIRST MANIFESTATION OF AMYLOIDOSIS IN FAMILIAL MEDITERRANEAN FEVER. *(E.)* Ravid, M.; Sohar, E. (Chaim Sheba Med. Ctr., Tel-Aviv, Israel). *Gastroenterology* 66(3):446-449, 1974.

Proteinuria, progressing to nephrosis, is the first clinical manifestation in virtually all cases of secondary amyloidosis and that associated with familial Mediterranean fever. Two cases of familial Mediterranean fever are described in which severe intestinal malabsorption was the presenting symptom of amyloidosis. In neither patient, one a 20-yr-old male and the other a 24-yr-old male, had there been previous evidence of renal involvement. Both patients received oral tetracycline. One of them gained some weight on tetracycline and a high-protein low-residue diet, but the degree of steatorrhea remained unchanged. Amyloidosis, which was demonstrated on rectal biopsy in both patients, was probably the sole cause of the intestinal malabsorption. Thus, clinicians should be aware of the possibility of amyloidosis being the cause of malabsorption, even in patients who show no evidence of renal damage.

LARGE INTESTINE

1 LIFE WITH A CONVENTIONAL ILEOSTOMY. *(E.)*
Bone, J.; Sorensen, F. H. (Aarhus Kommune-
pital, Denmark). *Dis. Colon Rectum* 17(2):194-
, 1974.

ollow-up study was made of 52 patients (23 men
29 women) who had undergone proctocolectomy and
ventional ileostomy for ulcerative colitis (50
es), familial polyposis (1 case), and congenital
acolon (1 case). Patients were interviewed
ut stomal function, working capacity, social adap-
ion, and sex life. The quality of life was con-
ered normal in 49 of these 52 patients. Two pa-
nts had intractable skin problems, and 1 was un-
e to adapt emotionally to a conventional ileostomy.
plications of the ileostomy included skin excoriation (16 cases), ileostomy stenosis (6 cases), stomal recession (2 cases), and minor hernias around the ileostomy (4 cases). After instruction in the use of either the karaya ring or aluminium hydroxide gel and karaya rubber powder, skin problems cleared up in 12 of 16 patients. Two patients with retracted ileostomies required surgery to cure their skin problems. The mucosa had not been everted and sutured to the skin at the time of surgery in all patients who developed ileostomy stenosis. Although 9 patients were receiving disability pensions, only 3 were receiving pensions for reasons related to the ileostomy and 2 of these appeared fit and healthy. The 52 ileostomy patients were distributed in approximately the same social levels as the normal population, and there was no great change after surgery although some of

the men had higher social status because of their greater working capacity. The ileostomy caused or contributed to divorce in 3 cases. Of the 38 married patients, only 1 had marital problems because her husband was unable to accept the ileostomy. Sexual function remained unchanged after surgery in 17 of the 23 men and in 21 of the 29 women. Six patients had married after ileostomy, and 6 had become pregnant. It is suggested that Kock's continent ileostomy might benefit patients who fail to adapt to conventional ileostomy.

4602 FLUOROURACIL, IMIDAZOLE CARBOXAMIDE DIMETHYL TRIAZENO, VINCRISTINE, AND BISCHLOROETHYL NITROSOUREA IN COLON CANCER. *(E.)*

Falkson, G.; VanEden, E. B.; Falkson, H. C. (H. F. Verwoerd Hosp., Pretoria, South Africa). *Cancer* 33(5):1207-1209, 1974.

A randomized clinical trial was undertaken comparing the effects of (1) fluorouracil (15 mg/kg/day i.v. for 5 days each month); and (2) fluorouracil (10 mg/kg/day i.v. on days 1 to 5; imidazole-4-carboxamide, 5-(3,3-dimethyl-1-triazeno) (3 mg/kg/day i.v. on days 1 and 2); vincristine (0.025 mg/kg/day i.v. on day 1); and 1,3-bis-(2-chloroethyl)-1-nitrosourea (1.5 mg/kg i.v. on day 1) on metastulic colon cancer. Courses for patients in group (1) and (2) were repeated at monthly intervals if hematologic toxicity permitted for as long as improvement continued or the disease remained static. In group (2) the maximum dose given was calculated on ideal body weight. Of 24 patients in group (1), complete remission occurred in 2, partial remission in 4, improvement in 3, no change in 4, and progressive disease in 11. Of 28 patients randomized to group (2), complete remission occurred in 4, partial remission in 8, improvement in 4, no change in 2, and progressive disease in 10. The worthwhile response rate in patients receiving fluorouracil was therefore 25%, while that in the group receiving the four-drug combination was 42.8%. Hematologic toxicity was comparable in the 2 groups, while nausea and vomiting were much more severe in those patients receiving the four-drug combination. Alopecia occurred in all patients on the four-drug combination who received more than 2 courses of treatment. Although administration of 5-fluorouracil alone is more acceptable to the patients, the four-drug combination should be considered for young patients with metastatic colon cancer who can tolerate its greater toxicity.

4603 PATHOGENESIS OF HYPERPLASTIC POLYPS OF THE COLON: A HYPOTHESIS BASED ON ULTRASTRUCTURE AND IN VITRO CELL KINETICS. *(E.)*

Hayashi, T.; Yatani, R.; Apostol, J.; Stemmermann, G. N. (Kuakini Hosp., Honolulu, Haw.). *Gastroenterology* 66(3):347-356, 1974.

Light and electron microscope examinations were performed on 45 polyps taken from segments of 19 colons removed for carcinoma, polyp, or diverticulitis in organ cell culture. The normal renewal cycle of the intestinal epithelium was characterized by the proliferation of stem cells in the basal portions of the crypts, migration of maturing cells toward the surface, and extrusion of the mature cells from the surface into the gut lumen. The morphology of the hyperplastic polyp and its *in vitro* cell kinetics indicate that it results from a disturbance of this cycle so that detachment of the mature cells is delayed or impeded so that the retained epithelium becomes hypermature. The morphological features which support this hypothesis are the superficial location of maximal change, cell elongation, an increase in the number and length of the microvilli, accentuation of the lateral intercellular interdigitations, and an increase in the breadth of the basal lamina attachment. Cell kinetics studies demonstrated that the mode of cell renewal in polyps is the same as in normal mucosas, but with longer turnover times and delayed migration.

4604 PANETH CELL METAPLASIA IN DISEASES OF THE COLON AND RECTUM. *(E.)*

Symonds, D. A. (Massachusetts Gen. Hosp., Boston). *Arch. Pathol.* 97(6):343-347, 1974.

The colonic distribution of Paneth cells was studied in sections of normal colon and rectum obtained from 20 adults and 10 children, and these findings were compared with those obtained on segments of colon from 287 patients with a variety of diseases of the colon and from 7 patients with cystic fibrosis. In normal colon Paneth cells were confined to the cecal mucosa near the ileocecal valve in the 5 specimens (2 adults and 3 neonates) in which they were found. Many Paneth cells were detected in specimens from 37 of the 40 patients with ulcerative colitis, 29 of 32 patients with solitary juvenile polyps of the sigmoid and rectum, 23 of the 50 patients with villous adenomas in the rectosigmoid, and many of the 35 patients with colloid (mucinous) adenocarcinomas. Moderate numbers of Paneth cells were found in specimens from 2 of 7 patients with cystic fibrosis and all 4 patients with amebic colitis. Only a few Paneth cells were present in specimens from 7 of the 30 patients with diverticulitis, 4 of 45 with nonmucinous carcinomas, and 12 of 50 with adenomatous polyps. With the exception of ulcerative colitis, in which Paneth cells were sometimes associated with decreased numbers of goblet cells, Paneth cells were consistently associated with goblet cell hyperplasia and increased mucin deposition and were most numerous where mucin deposition was most pronounced, as around colloid carcinomas. These findings suggest that Paneth cells may control the viscosity or related physicochemical properties of gastrointestinal mucins. Such a function could aid in eliminating increased mucins or abnormal mucus deposits which were prominent morphological features in some of the diseases studied.

4605 RECTAL PRESSURE IN CHILDREN WITH PROLAPSE RECTUM. *(E.)*

Jha, B. N.; Prakash, O.; Choudhary, D. K.; Prasad, P. B. (Patna Med. Coll. Hosp., India). *Indian Pediatr.* 10(10):595-598, 1973.

Rectal pressure studies were done in 20 children, aged 6-11 yr, with prolapse of the rectum. Changes observed in lying down, commode, and squatting postures, with or without straining, were compared. In a prone posture, the average rectal pressure was bout the same in controls and in patients with rectal rolapse and normal sphincters. The pressure read-ngs doubled during straining in both groups. In he commode position, the average reading was 35 cm f water in controls and 44 cm in children with rec-al prolapse. The readings increased to 68 cm and 8 cm, resp. during straining. In the squatting osition, the average pressure was 49 cm in controls nd 54 cm in patients with prolapse. The pressures ose to 107 and 110 cm, resp. with straining. Among atients with prolapse who had patulous sphincters, owever, average pressure values of 79 and 30 cm were easured with and without straining resp. in squatting osition. The results suggest that: (1) the squat-ing position and straining on squatting generates igher intrarectal pressures than the prone or commode ostures; (2) the rise in intrarectal pressure is omparable in both normal subjects and those with ectal prolapse; and (3) there is a fall in pressure n patients with patulous anal sphincters. It is oncluded that squatting should be avoided by children ith rectal prolapse. The use of Gallow's splint as helpful in 6 patients on whom it was tested.

606 METACHRONOUS COLORECTAL POLYPS: COMPARISON OF DEVELOPMENT OF COLORECTAL POLYPS ND CARCINOMAS IN PERSONS WITH AND WITHOUT HISTORIES F POLYPS.

(E.) Brahme, F.; Ekelund, G. R.; Nor-en, J. G.; Wenckert, A. (San Diego Univ. Hosp., alif.). *Dis. Rectum Colon* 17(2):166-171, 1974.

o determine whether the presence of a colorectal olyp implies an increased risk of subsequent colorec-al carcinoma or benign polyps, follow-up examinations ere performed on 123 patients who had had a colo-ectal polyp diagnosed radiologically by the double ontrast method between 1955 and 1957. All patients ere more than 18 yr old and had resided in Malmo, weden during the entire period of the investigation. iagnosis of the index polyp had been confirmed by adiological examination on at least one additional ccasion, or by biopsy or autopsy. The index polyp as not associated with a previous or simultaneous arcinoma or with any carcinoma found within 5 yr fter the original radiological diagnosis had been stablished. These 123 patients were compared with 23 age- and sex-matched controls with radiographi-ally normal findings between 1955 and 1957. One r more new polyps were diagnosed in 26 patients with olorectal polyps and in 11 controls. The difference etween these 2 groups is significant. When patients ith only metaplastic, mesenchymal, or inflammatory olyps were excluded, 24 patients (16 men and 8 wo-en) had developed new polyps. More than one polyp as found in 7 (29%) of these 24 patients, and a otal of 39 new polyps were diagnosed. Of these 39 ew polyps, 59% were found in the left hemicolon nd rectum. Three patients developed adenocarcinomas f the large intestine 65 months to 8 yr after diag-osis of the index polyp. No colorectal carcinomas eveloped among controls. It is concluded that the resence of one or more colorectal polyps implies an ncreased risk for the patient to develop additional olyps. No statistical conclusions can be drawn about hether the presence of colorectal polyps increases he risk of developing cancer of the large intes-ine.

4607 ENDOCAVITARY IRRADIATION IN THE CURATIVE TREATMENT OF EARLY RECTAL CANCERS.

(E.) Papillon, J. (Leon Berard Ctr., Lyon, France). *Dis. Colon Rectum* 17(2):172-180, 1974.

Between 1951 and 1969, endocavitary irradiation was employed in the treatment of 152 patients with invasive adenocarcinomas of the rectum. Using the Phillips contact x-ray machine, 3000-4000 rads, given over a 3-min period, were administered every 7-10 days for 4-6 weeks (total doses of 9000-15,000 rads). This method is applicable only if the tumor is (1) small, (2) noninfiltrating, (3) fairly well-differentiated, and (4) low enough in the rectum so that the entire mass is accessible. Of 106 patients treated between 1951 and 1966 and followed for more than 5 yr, 75 (70%) are alive, well, and have no evidence of malignancy. Irradiation alone was administered to 71 patients, while 4 had to undergo surgery after radiotherapy failed. Local failure occurred within the first 2 yr in 12 patients who underwent radical surgery: 8 died and 4 were alive and free of malignancy after 5 yr. Two patients had rapid recurrences of colloid carcinomas and, despite surgery, died of metastases within the first 2 yr. Within the first 5 yr there were 15 deaths unrelated to the primary malignancy and 16 deaths from malignant disease. Endocavitary irradiation was used to destroy the exophytic part of the tumor and a radium implant was applied to the base of the tumor 6 weeks later in 20 of the 46 patients treated between 1967 and 1969. Of these 46 patients who were followed for 2-5 yr, 39 are alive with no evidence of disease 4 yr after treatment. There were 9 failures. Of the 8 who underwent surgery, 4 are alive and well 2-5 yr later. One patient was inoperable and 2 died of intercurrent disease. There are very few complications and no risk of mortality associated with endocavitary irradiation. The procedure is well tolerated, even in poor-risk and senile patients. However, tumors should meet the above criteria and careful follow-up of patients is necessary.

4608 IRRITABLE COLON: A PRELIMINARY STAGE OF COLONIC DIVERTICULOSIS.

(E.) Thijn, C. J. P. (Univ. Hosp., Groningen, Netherlands). *Radiol. Clin. Biol.* 42(6):468-481, 1973.

Data from the literature and from personal observations indicate that an irritable colon syndrome, which persists for years, is a precursor of colonic diverticulosis, which develops fully in the course of a few decades. This is supported by the age distribution of patients with these 2 conditions. The mean age of 37 patients with irritable colon was 46 yr, while that of 70 patients with colonic diverticulosis was 64 yr. In addition, no sharp differentiation between these conditions can be made on the basis of symptoms, suggesting that colonic diverticulosis and irritable colon are different phases of the same clinical entity. Irritable colon is initially dominated by disorders of motility, giving rise to small diverticula which are then enlarged as a result of increased intraluminal pressure. Two case reports are presented. In the first, diverticula were found only proximal to a stenosing neoplasm in the transverse colon. In the second, 3 consecutive colon studies showed the development and subsequent slight reduction in size of a number of small diverticula. Improvement may have been due to the use of a high-residue diet. The principal causes of irritable colon are assumed to be low-residue nutrition, emotional stress, and dysregulation between the sympathetic and parasympathetic nervous system. The recommended method of investigation is dual-contrast radiography, with the aid of which even incipient diverticulosis can be demonstrated.

4609 ROENTGENOLOGY OF INFECTIOUS COLITIS.

(E.) Farman, J.; Rabinowitz, J. G.; Meyers, M. A. (State Univ. New York-Downstate Med. Ctr., Brooklyn). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2): 375-381, 1973.

Barium enema examination in 7 patients (2 men and 5 women, aged 21-56 yr) with infectious colitis due to *Salmonella* or *Shigella* revealed diffuse colonic involvement in 2 and segmental colonic involvement in 5. One patient with diffuse disease had an atonic colon with loss of the normal haustral pattern. A small bowel examination in this patient showed ulceration, edema, and dilation of the duodenum, jejunum, and ileum. The second patient with total colonic involvement manifested a dilated edematous colon and superficial ulcerations in the sigmoid. The descending colon was a frequent site of segmental colitis; rectal involvement was variable and in some cases skip lesions alternated with areas of normal bowel. Spasm, edema, and ulceration were the main roentgenologic features in the involved areas. At times the ulcers were superficial and resembled those seen in classical colitis; on other occasions the ulcers were deep and resembled those visualized in Crohn's disease. Colonic changes were reversible in all patients who responded to therapy. Thus the reversibility of the ulcerations, spasm, and edema of acute colitis should differentiate infectious colitis from both Crohn's disease and ulcerative colities.

4610 A PROSPECTIVE STUDY OF APPENDECTOMY AND PREDISPOSITION TO CANCER.

(E.) Moertel, C. G.; Nobrega, F. T.; Elveback, L. R.; Wentz, J. R. (Mayo Clin., Rochester, Minn.). *Surg. Gynecol. Obstet.* 138(4):549-553, 1974.

The incidence of cancer among 1779 patients who underwent appendectomy between 1925 and 1944 was compared with that among 1943 controls who had never undergone appendectomy. The appendectomy patients included 697 in whom the operative indication was acute appendicitis and 617 in whom it was chronic appendicitis. A total of 386 people in the two groups developed cancer. There was no meaningful difference in the overall occurrence of cancer between the two groups, and the standard morbidity ratios for the two groups showed close agreement. Neither the age at appendectomy nor the occurrence of chronic versus acute appendicitis was correlated with increasing risk of cancer. In addition, there was no evidence that tonsillectomy alone or in combination with appendectomy had any influence on the occurrence of cancer. The practice of incidental appendectomy during abdominal surgical procedures should be continued whenever this can be done conveniently without increasing operative risk.

4611 MANAGEMENT OF PSEUDO-OBSTRUCTION OF THE COLON.

(E.) Norton, L.; Young, D.; Scribner, R. (Denver Gen. Hosp., Colo.). *Surg. Gynecol. Obstet.* 138(4):595-598, 1974.

Pseudo-obstruction of the right colon (Ogilvie's syndrome) with splitting of the *teniae coli* in the right colon was encountered in 4 male alcoholics, aged 41-66 yr, who had been hospitalized for nonabdominal disease. Symptoms included abdominal distension, in some cases without pain, vomiting, or tenderness. Roentgenograms of the abdomen showed a distended colon without air-fluid levels; the distribution of colonic gas was segmental. The degree of small intestinal distension was variable. Moderate leukocytosis and normal serum electrolytes were noted in all 4 patients. The significant difference between these patients and others reported to have Ogilvie's syndrome is that all 4 of these patients had longitudinal splitting of *teniae coli* along the right colon. In one patient the mucosa had perforated and bulged through the separated *teniae* fibers. In the other 3, no perforation was evident, but the extruded mucosa probably formed an inadequate barrier to coliform organisms passing from the intestinal lumen into the peritoneal cavity. This is suggested by the course of one patient whose intestine was not resected after the split *teniae* were repaired. This patient apparently died of sepsis resulting from peritonitis. Colectomy and fecal diversion by ileostomy are recommended for patients with pseudo-obstruction of the colon and splitting of the *teniae coli*.

4612 PERSISTENT ENTEROCUTANEOUS FISTULA ASSOCIATED WITH INTRAPERITONEAL METALLIC MERCURY.

(E.) Efrusy, M. E.; Dobbins, III, W. O. (George Washington Univ. Med. Ctr., Washington, D. C.). *Am. J. Dig. Dis.* 19(4):373-377, 1974.

A 52-yr-old black female was admitted to the hospital for evaluation of an ileocolocutaneous fistula to the left lower abdomen associated with a purulent discharge. Four years previously she had had a partial colectomy with an ileosigmoid anastomosis for treatment of bleeding diverticulosis coli: the postoperative period was complicated by wound infection requiring drainage and paralytic ileus requiring decompression with a Cantor tube. A mercury-containing balloon attached to the Cantor tube apparently ruptured 2 days after intubation when a scout film of the abdomen revealed a very dense radiopaque material, believed to be mercury, free in the peritoneal cavity. Laboratory data at the later hospital admission were normal. A plain film, however, showed metallic densities in the left lower abdomen. At sigmoidoscopic examination several small globules of mercury were seen in the rectum; the mercury was also grossly visible on histological sections. The patient was treated conservatively and discharged. Six weeks later, she returned stating that the fistula continued to drain intermittently. Blood mercury levels were 20 μg/100 ml, normal being 0 to 7 μg. There was no evidence of systemic toxicity in this patient. While metallic mercury is harmless in the intact gut, it can have adverse effects when it gains entrance to the peritoneal cavity through a break in the mucosa of the intestinal tract.

4613 APPENDICEAL INTUSSUSCEPTION: AN UNUSUAL CAUSE OF PAINLESS RECTAL BLEEDING. *(E.)* Brewer, R. J.; Wangensteen, S. L. (Univ. Virginia Med. Ctr., Charlottesville). *Am. Surg.* 40(5): 319-320, 1974.

A case of intermittent painless rectal bleeding caused by intussusception of the appendix is presented. The patient, a 24-year-old woman, presented with bloody diarrhea, tachycardia, dizziness, and syncope. The only abnormal laboratory finding was a hematocrit of 30. Proctoscopy, air contrast barium enema, barium swallow, and upper gastrointestinal series demonstrated no abnormalities. Five months later, the patient returned with bloody stools; again, no abnormalities were demonstrated. Eight months after that, she again presented with bloody diarrhea. An air contrast barium enema demonstrated a polypoid mass which was intracecal at first, then extracecal, suggesting that an intussusception of the appendix had been reduced during the procedure. Because an intracecal mass was palpated at laparotomy, the terminal ileum and cecum were resected, and an end-to-side ileocolostomy was performed; the patient had no further rectal bleeding. Pathological examination of the appendix revealed a mucosal ulcer and two polypoid projections in the proximal lumen of the markedly thickened appendix. The polypoid areas and mucosal ulcer showed acute and chronic inflammation.

4614 SYMPTOMATIC MUCOCELE OF THE APPENDIX DIAGNOSED PREOPERATIVELY. *(E.)* Koster, L. H. (Western Pennsylvania Hosp., Pittsburgh). *Am. J. Surg.* 127(5):582-584, 1974.

An unusual case of preoperatively diagnosed mucocele of the appendix is presented. The patient, a 39-year-old male, was admitted to the hospital because of severe pain and tenderness in the right lower abdominal quadrant without nausea, vomiting, or diarrhea. Guarding was present, bowel sounds were hypoactive and, on rectal examination, a rigid, smooth, slightly tender mass was palpable on the right. Several small lateral calcifications on the right side of the abdomen were detected in a flat plate of the abdomen. The appendix did not fill during a barium enema, and there was reflux into the terminal ileum. The appendix was retrocecal and acutely inflammed at operation. A diagnosis of acute appendicitis and proximal mucocele of the appendix with fibrosis and focal calcification was established on pathological examination. It is important that mucocele be recognized before surgery since it is necessary to avoid spillage of the cystic contents at operation. These lesions may be malignant, and error might result in the formation of multiple cysts and intestinal obstruction.

4615 BLADDER DYSFUNCTION: A SIGN OF OCCULT COLONIC CARCINOMA. *(E.)* Kase, S.; Goldfarb, M. (no affil.). *Dis. Colon Rectum* 17(2): 238-240, 1974.

Persistent antecedent urinary tract symptoms and no gastrointestinal symptoms were observed in 15 patients who were finally found to have colonic carcinoma. Thirteen of the 15 patients had rectal or sigmoidal lesions. Only 2 patients were finally diagnosed as having right colonic carcinomas. Ages ranged from 54 to 76 years (average 65 years). The urologic symptoms included prostatitis, uremia, pyuria, persistent cystitis, frequency, nocturia, poor stream, urinary retention, and hematuria. The colonic carcinoma was treated by: sigmoidal resection (10 cases), right colectomy (2 cases), abdominoperineal resection (2 cases), and no surgery (1 case). The similarity in innervation, overlap of vascular supply, and the juxtaposition of the anatomy between the lower urinary tract and the lower bowel tend to make these organ systems interrelated in many clinical syndromes. All patients who present with intractable pyuria, recurrent prostatitis, or recurrent hematuria with no obvious urologic disease should undergo lower gastrointestinal investigation to rule out carcinoma of the colon.

4616 TUMOR-LIKE LESIONS OF THE CECUM FOLLOWING INVERSION OF THE APPENDIX. *(E.)* Mylarniemi, H.; Perttala, Y.; Peltokallio, P. (2nd Dept. Surg., Univ. Helsinki, Finland). *Am. J. Dig. Dis.* 19(6):547-556, 1974.

LARGE INTESTINE

Ulcerative Colitis

4672 PROPERTIES OF STRAINS OF ESCHERICHIA COLI CARRIED IN DIFFERENT PHASES OF ULCERATIVE COLITIS. *(E.)* Cooke, E. M.; Ewins, S. P.; Hywel-Jones, J.; Lennard-Jones, J. E. (St. Bartholomew's Hosp., London, England). *Gut* 15(2):143-146, 1974.

Strains of *Escherichia coli* from the feces of patients with active ulcerative colitis and with colitis in remission were examined for hemolysin and necrotoxin production. Cultures from 63 patients with active colitis grew hemolytic *E. coli* in 23 (37%) as compared with 24 (21%) from 115 patients whose disease was in remission. The corresponding proportions for necrotoxin producing strains were 22% and 12%. Of 35 patients investigated both in relapse and remission of the colitis, 14 changed their carriage of hemolytic *E. coli*. Of these 14, 13 carried hemolytic organisms in relapse but not in remission and 1 carried hemolytic organisms in remission but not in relapse. At weekly intervals for 28 weeks, strains of *E. coli* were also examined from specimens of feces from 19 patients. In 4 patients who developed a relapse of the disease during this time, the acquisition of hemolytic or necrotoxic *E. coli* strains followed rather than preceded the onset of the attack. Hemolytic and necrotoxic strains were found most often among these 19 patients when blood was regularly present in the feces. These results suggest that conditions in the bowel during a relapse of colitis favor the presence of hemolysin- and necrotoxin-producing organisms, rather than that these organisms cause the relapse. Of 50 strains of *E. coli* from patients treated with sulphasalazine tested for sensitivity to sulfapyridine, 49 were resistant. No clear relation was established between the activity of the colitis and the presence of any of the 27 serotypes of *E. coli* examined.

4673 TOTAL BODY WATER AND TOTAL EXCHANGEABLE SODIUM IN PATIENTS AFTER ILEORECTAL ANASTOMOSIS. *(E.)* Hill, G. L.; Watts, J. McK.; Iseli, A.; Clarke, A. M.; Hughes, E. S. R. (Univ. Otago Med. Sch., Dunedin, New Zealand). *Br. J. Surg.* 61(3):189-192, 1974.

Total body water and total exchangeable sodium were measured in 29 patients (14 males and 15 females, aged 21-74 yr) who had undergone subtotal colectomy with ileorectal anastomosis for chronic ulcerative colitis more than 1 yr previously and in a control group of 28 persons. There was no significant difference in the state of hydration or in the total exchangeable sodium between the patients and the controls. No significant difference in the 24-hr urinary volume and sodium excretion was noted in either group.

These findings contrast with dehydration and sodium depletion previously demonstrated in ileostomy patients. Fecal loss of sodium in patients with ileorectal anastomosis was less than in patients with ileostomies. These findings suggest that ileorectal anastomosis carries with it less risk of long-term fluid and electrolyte depletion than ileostomy. It is suggested that in patients with ileorectal anastomosis the rectum retains some useful absorptive function.

4674 HL-A-W27 -- A USEFUL DISCRIMINATOR IN THE ARTHROPATHIES OF INFLAMMATORY BOWEL DISEASE. *(E.)* Morris, R. I.; Metzger, A. L.; Bluestone, R.; Terasaki, P. I. (Wadsworth Hosp. Ctr., Los Angeles, Calif.). *N. Engl. J. Med.* 290(20):1117-1120, 1974.

The relation between the W27 antigen and the arthropathy associated with inflammatory bowel disease, i.e., peripheral joint inflammation and spondylitis, was studied in a group of 31 patients with either Crohn's disease or chronic ulcerative colitis, with or without arthritis. Only the patients with inflammatory bowel disease and spondylitis had the W27 antigen (6 of 8 cases) compared to a 6% frequency of the antigen in 267 white controls. In addition, 2 patients with spinal involvement (both W27 positive) had a peripheral seronegative arthropathy associated with the inflammatory bowel disease. Iritis was present in 4 (all W27 positive) of 8 patients with spondylitis and in 1 (W27 negative) of 23 without spondylitis. Thus, 50% of the patients with inflammatory bowel diseases and spondylitis had iritis as opposed to 4% of the subjects without spondylitis. Of 5 patients with iritis, 4 had spondylitis and were W27 positive. These data strongly support the clinical impression that these are 2 distinct arthropathies with differing pathogenetic mechanisms. It is suggested that the presence of peripheral arthritis alone may arise due to some hypersensitivity phenomenon related to bowel inflammation. The development of iritis may result from the association of iritis with W27-positive ankylosing spondylitis rather than from an extraintestinal manifestation of the primary disease. It is projected that ankylosing spondylitis may develop in nearly half of the W27 positive population with ulcerative colitis, whereas 1 of 6 W27-positive patients with Crohn's disease may progress to spondylitis. Thus W27 antigen is a useful clinical discriminator between the arthropathies of inflammatory bowel disease and may define patients markedly at risk of developing spondylitis and perhaps iritis, but not peripheral arthritis.

4675 ARTHRITIS ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE IN CHILDREN. *(E.)* Lindsley, C. B.; Schaller, J. G. (Univ. Washington Med. Sch., Seattle). *J. Pediatr.* 84(1):16-20, 1974.

Arthritis occurred in 23 of 136 (17%) children and teenagers with inflammatory bowel disease, in 18 of 86 (21%) patients with ulcerative colitis, and 5 of 50 (10%) with granulomatous bowel disease. Peripheral arthritis occurred in 18 children which characteristically affected only a few large joints and was of brief duration and benign outcome. Spondylitis occurred in 5 boys and was progressive and inseparable clinically from ankylosing spondylitis. There was little relation between the occurrence of arthritis and the severity of the underlying bowel disease. Anemia and growth retardation occurred frequently. Mucocutaneous lesions were associated with peripheral arthritis but not with spondylitis. No patient had iridocyclitis. The possibility of bowel disease should be considered in children presenting with arthritis, particularly if few joints are involved and episodes of arthritis are transient, and particularly if gastrointestinal complaints, mucocutaneous lesions, anemia, or growth retardation are associated with pauciarticular arthritis. In children with arthritis and inflammatory bowel disease, the possibility of ankylosing spondylitis should be considered and radiographs of the sacroiliac joints followed. Therapy for the peripheral arthritis of inflammatory bowel disease consists of recognition of the generally benign nature of this complication and treatment of the underlying bowel disease. Spondylitis of inflammatory bowel disease, however, does not regress; and early recognition and appropriate therapy of the arthritis with anti-inflammatory drugs and physical therapy are necessary to prevent ultimate musculoskeletal deformity.

4676 IMMUNOSUPPRESSION IN THE TREATMENT OF INFLAMMATORY BOWEL DISEASE. I. CHANGES IN LYMPHOID SUB-POPULATIONS IN THE BLOOD AND RECTAL MUCOSA FOLLOWING CESSATION OF TREATMENT WITH AZATHIOPRINE. *(E.)* Campbell, A. C.; Skinner, J. M.; Hersey, P.; Roberts-Thomson, P.; MacLennan, I. C. M.; Truelove, S. C. (Radcliffe Infirm., Oxford, England). *Clin. Exp. Immunol.* 16(4):521-533, 1974.

Lymphoid subpopulations in the blood and rectal mucosa were studied in 3 patients with ulcerative colitis and 3 with Crohn's disease who had been treated for 3 to 4 1/2 yr with 100-150 mg/day azathioprine. Serial assays were performed to observe the changes occurring up to 12 weeks after treatment with azathioprine was discontinued. While the patients were on the drug, 2 lymphoid populations were markedly depressed. These were the plasma cells of the rectal lamina propria and blood lymphocytes with cytotoxic activity against antibody-sensitized target cells ('K' cells). After discontinuation of azathioprine, both populations rapidly increased to near normal levels by 12 weeks. Most of the recovery occurred within 3 to 5 weeks. There was no significant change in circulating immunoglobulin-staining cells which could be attributed to the drug. Nor was azathioprine shown to have any effect on the mitotic response of lymphocytes to phytohemagglutinin. Three patients, however, gave very low or erratic responses to phytohemagglutinin, which may have been related either to their disease or to steroid therapy (2 were receiving prednisolone p.o. and 1 was using predsol enemas). It is suggested that the cytotoxic action of azathioprine is most pronounced on rapidly proliferating cell populations such as antibody-dependent cytotoxic lymphocytes and plasma cells.

4677 TOXIC MEGACOLON IN ULCERATIVE COLITIS. *(E.)* Binder, S. C.; Patterson, J. F.;

Glotzer, D. J. (Tufts Univ., Boston, Mass.). *Gastroenterology* 66(5):909-915, 1974.

Of a total of 220 patients treated for ulcerative colitis between 1961 and 1973, 18 (13 men and 5 women, aged 18-69 yr) developed toxic megacolon. Diagnosis was established by clinical examination, sigmoidoscopy, and the appearance of plain roentgenograms of the abdomen. Fluid, electrolyte, and serum albumin deficits were corrected; transfusions were given as needed for anemia; and systemic antibiotics and parenteral steroids (300-400 mg/day hydrocortisone or 40-80 U/day adrenal corticotropin) were administered to all but 5 patients who were operated on immediately because of suspected or actual perforation. Only 1 patient improved sufficiently on medical therapy so that surgery was not required. Two other patients recovered for a short time before recurrence of toxic megacolon necessitated surgery. The colon was perforated at surgery in 3 patients and perforated during surgery in 2 others. Subtotal colectomy, ileostomy, and sigmoid mucous fistula were performed on 7 patients subtotal colectomy, ileostomy, and Hartmann turn-in of the rectal stump on 2; and total proctocolectomy with ileostomy was performed on 8. In contrast to the average reported mortality of 23.1% in patients with ulcerative colitis who develop toxic megacolon, only 1 (5.6%) of these patients died. Death resulted from bone marrow aplasia and resultant hemorrhagic diathesis secondary to chloromycetin therapy administered for generalized sepsis. Sepsis was responsible for 7 of the 10 major complications attributed directly to the operation. All patients who survived surgery are alive and well 1-13 yr later. Early surgical intervention is advocated for these patients to prevent colonic perforation and progressive metabolic deterioration that prolonged medical management may produce. Colectomy, rather than decompressive enterostomy, is recommended as the procedure of choice.

4678 HIGH DOSE PREDNISONE TREATMENT IN SEVERE ULCERATIVE COLITIS.

(E.) Kristensen, M.; Koudahl, G.; Fischerman, K.; Jarnum, S. (Rigshospital, Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):177-183, 1974.

High dose prednisone therapy (80-160 mg/day) with supportive blood transfusions and infusions of serum proteins, amino acids, and electrolytes was given to 31 patients (17 females and 14 males, aged less than 20 to over 60) with acute life-threatening ulcerative colitis of less than 3 months up to 2 yr duration. Therapy was continued for a period of 1 to 12 months, (average 5 months). Of the 31 treated patients, 14 went into remission. In 17 patients the therapy failed and colectomy was performed. Of the 17, 9 were subjected to 'acute' operation because of increasing hemorrhage, toxic megacolon, suspected perforation, or rapid clinical deterioration. There were 4 deaths: 3 patients died postoperatively and 1 responded to steroid therapy but died of pulmonary embolism. During the follow-up study, which ranged from ½ to 7 yr, 3 patients who responded initially to prednisone treatment were operated upon. Intensive medical therapy including a high dose prednisone treatment in severe acute ulcerative colitis appeared justified since it saved the colon in 45% of the cases. However, meticulous surveillance, experience, and close collaboration between internist and surgeon are prerequisites for this type of treatment.

4679 ULCERATIVE COLITIS IN THE JEWISH POPULATION OF TEL-AVIV JAFO. I. EPIDEMIOLOGY.

(E.) Gilat, T.; Ribak, J.; Benaroya, Y.; Zemishlany, Z.; Weissman, I. (Ichilov Hosp., Tel-Aviv, Israel). *Gastroenterology* 66(3):335-342, 1974.

An epidemiological study of ulcerative colitis was performed in the Jewish population of Tel-Aviv Jafo during the period from 1961 to 1970. The annual incidence rate averaged $3.66/10^5$ population, and the prevalence was $37.4/10^5$. These figures are significantly lower than those in comparable studies conducted in Oxford, England, Rochester, Minnesota and Copenhagen, Denmark, suggesting that the disease is less frequent in Jews in Tel-Aviv. The disease was most prevalent in European and American born members of the Jewish Population in Tel-Aviv (37.3) and, by decreasing order, in Israeli born (25.7), Asian born (18.9), and African born (18.5). The female-male ratio was 0.80; the female-male ratio in the population, 1.004. The age of onset of disease peaked between 15 and 25 yr with a second smaller peak between 30 and 40. While no rise in incidence could be demonstrated over the time period of the study, the annual rate did fluctuate. The percentage of ulcerative colitis patients who were never hospitalized was 14.8%. It is felt that, due to the improved diagnostic methods and earlier diagnosis of the disease, many people are treated as outpatients and never admitted to hospitals. Thus the use of only hospitalized cases in an epidemiological study of ulcerative colitis is not valid.

4680 SURGICAL MANAGEMENT OF TOXIC DILATATION OF THE COLON IN ULCERATIVE COLITIS.

(E.) Scott, Jr., H. W.; Sawyers, J. L.; Gobbel, Jr., W. G.; Graves, H. A.; Shull, H. J. (Vanderbilt Univ. Med. Ctr., Nashville, Tenn.). *Ann. Surg.* 179(5): 647-656, 1974.

After preliminary medical therapy, ileostomy with single- or two-stage proctocolectomy was done in 16 patients (9 women and 7 men, aged 20-65 yr) with ulcerative colitis and toxic dilatation of the colon. There was a single fatality in a patient who had multiple colonic perforations at operation; the patient died in uremia with multiple abscesses, peritonitis, and *Pseudomonas* septicemia. Another patient (an 18-yr-old man) was successfully treated by Turnbull's operation of loop ileostomy with "blow-hole" transverse colostomy. Four of the 16 surviving patients made totally uneventful recoveries with primary healing of wounds and no complications. Two others made equally smooth recoveries except for a mild urinary infection in 1 and transitory per-

al palsy in the other. Recovery in the 10 other
ients was delayed by complications including ab-
inal abscess (5), wound abscess (4), urinary in-
tion (3), rectal bleeding (3), wound dehiscence (2),
ineal infection (2), and coma (2). Follow-up res-
s after 1-10 yr are excellent. Early recognition of
toxic dilatation syndrome in ulcerative colitis is
erative. Resuscitative treatment should be given
a life-threatening emergency basis and should in-
de parenteral fluids, electrolytes, blood, broad
ctrum antibiotics, vitamins, steroids, and naso-
tric suction. Operation, whether ileostomy with
octo)colectomy or Turnbull's procedure, should
carried out urgently after 12-24 hr of resuscita-
e treatment.

PANCREAS

8 NEW ONCOFETAL ANTIGEN FOR HUMAN PANCREAS.
(E.) Banwo, O.; Versey, J.; Hobbs, J. R.
stminster Hosp. Med. Sch., London, England).
cet 1(7859):643-645, 1974.

isera against stabilized homogenates of whole
an fetal pancreas were raised in rabbits and ab-
bed with normal adult pancreas and albumin. By
-dimensional immunoelectrophoresis in agarose
taining antiproteases, a characteristic peak was
wn in sera from 36 of 37 patients with carcinoma
the pancreas. It was also found against ex-
cts of fetal pancreas or adult pancreatic carcino-
. It was absent from sera of 38 other patients,
luding those with gut cancers (8 positive for
lonic carcinoembryonic antigen), hepatoma (2 posi-
e for α-fetoprotein), other causes of jaundice
), and acute (5) or chronic (12) pancreatitis.
was absent in extracts of fetal colon and fetal
er. Thus far the adsorbed antisera seem to de-
t an oncofetal antigen complex specific to pan-
as.

9 ULTRASTRUCTURAL STUDY OF INTRANUCLEAR
INCLUSIONS IN THE EXOCRINE PANCREAS IN
REYE'S SYNDROME. *(E.)* Collins, D. N. (New York State Dept. Health, Albany). *Lab Invest.* 30(3):333-340, 1974.

Electron microscope studies of organs from a child dying of Reye's syndrome led to the finding of previously unreported intranuclear inclusions in the pancreatic acinar cells. These bizarre inclusions were of varying size, number, and shape and occasionally presented a laminated appearance. They did not resemble any known infectious agent, although adenovirus type 2 was simultaneously isolated from the adrenal gland. Similar intranuclear inclusions were subsequently identified in pancreases obtained from 4 other documented cases of Reye's syndrome. Many lipid globules were present in the cytoplasm of hepatocytes and cells of the renal tubules and in the vascular epithelium of an abdominal lymph node, in the spleen and in adrenal and salivary glands. Although acinar cell nuclei of the salivary gland contained pseudoinclusions consisting of inverted nuclear membranes enclosing fragments of rough endoplasmic reticulum, no true inclusions were observed with characteristics similar to those in the pancreas. The pancreatic inclusions can be identified by light microscopy and may be a characteristic of Reye's syndrome. They were not found by light or electron microscopy in the pancreases from 3 children dying of unrelated diseases. It is hypothesized that the inclusions originate from cytoplasmic invaginations formed as a response to toxic injury of pancreatic acinar cells.

4690 CHEMOTHERAPY IN PANCREATIC CARCINOMA: 5 FLUOROURACIL (5FU) AND 1,3 BIS-(2 CHLORETHYL)-1-NITROSOUREA (BCNU). *(E.)* Lokich, J.; Chawla, P. L.; Brooks, J.; Frei, III, E. (Peter Bent Brigham Hosp., Boston, Mass.). *Ann. Surg.* 179(11):450-453, 1974.

Twenty patients with pancreatic carcinoma were given a 5-day course of 5-fluorouracil (10 mg/kg/day i.v.) followed by a 5-day course of 1,3 bis-(2 chlorethyl)-1-nitrosourea (40 mg/m^2/day i.v.). The 5-day courses were repeated at 6-8 week intervals. In 3 of the 20 patients the diagnosis was made by closed liver biopsy and no operative procedure was undertaken. Surgical bypass was performed in 7 patients, total pancreatectomy in 3, partial pancreatectomy in 1, and exploratory laparatomy with biopsy only in 6. Therapeutic responses could not be evaluated because of early death in 5 cases. Two patients had complete regression (lasting 31 and 13 months, resp.) as represented by total normalization of the liver scan and ultrasound examination and disappearance of intra-abdominal masses. Partial response (more than 50% tumor regression) was observed in 2 patients and persisted for 6 and 3 months, resp. In addition, stabilization occurred in 5 patients with lack of clinical progression for 3-12 months. Thus, 9 of 15 patients (60%) were clinically palliated by the administration combined chemotherapy. Toxicity, consisting primarily of gastrointestinal manifestations and bone marrow suppression, was less than that observed with the same agents administered alone.

Pancreatitis

4695 INTESTINAL MUCOSAL DISACCHARIDASES IN CHRONIC PANCREATITIS. *(E.)* Arvanitakis, C.; Olsen, W. A. (Kansas Univ. Med Ctr., Kansas City). *Am. J. Dig. Dis.* 19(5):417-421, 1974.

Disaccharidase activity was measured in the mucosa of the small intestine in 9 men, aged 42-50 yr, with chronic relapsing pancreatitis related to alcohol and in 6 men, aged 45-58 yr, with no evidence of gastrointestinal, pancreatic, or liver disease. A similar study was conducted in 6 men, aged 50-63 yr, with diabetes mellitus to rule out the possibility that diabetes, rather than pancreatic disease, accounted for the results. At the time of the study all of the patients with chronic pancreatitis were entirely asymptomatic, were eating a normal diet, and had normal serum amylase values. None of the patients was receiving pancreatic enzyme therapy. Sucrase and maltase activities were significantly higher in patients with chronic pancreatitis than in controls. They averaged 98 ± 7 μmol sucrose hydrolyzed/min/g protein *versus* 48 ± 9 in controls and 233 ± 10 μmol maltose hydrolyzed/min/g protein *versus* 163 ± 23 in controls. Lactase levels were the same in both groups. Patients with diabetes had, if anything, enzyme activities which were lower than those of the controls. Since nearly all of these patients had pancreatic insufficiency, it is suggested that a decrease in the intraluminal concentration of pancreatic enzymes may lead to a decrease in the rate of sucrase and maltase degradation in patients with chronic pancreatitis, allowing these enzymes to accumulate in the brush border membrane.

4696 FACTORS IN THE PATHOGENESIS OF EXPERIMENTAL ACUTE PANCREATITIS IN THE RAT. *(E.)*

st, A.; Dishon, T.; Rosenmann, R.; Boss, J. H. dassah Med. Sch., Hebrew Univ., Jerusalem, Israel). . *Surg. Res.* 5(5):348-361, 1973.

following solutions were injected under pressure o the pancreas of male albino rats via a duodenal ment which had been surgically obstructed: phy- logical saline; a 2% solution of bovine serum al- in (BSA); nephrotoxic serum; normal rabbit serum; ubilized immune complexes of inactivated rabbit i-BSA serum; inactivated rabbit anti-BSA serum; normal rat serum. Some of the rats receiving the ologous or heterologous protein solutions had been viously sensitized to the respective protein. d pancreatitis resulted from the introduction of ine. Pancreatitis also occurred in a group of m-operated, uninjected controls. The administra- n of homologous or heterologous protein solutions uced mild pancreatitis; prior sensitization did aggravate the inflammatory process. The injec- n of nephrotoxic serum or the preformed immune plexes induced severe pancreatitis. The animals eiving normal rabbit serum or anti-BSA serum de- oped mild pancreatitis, as did the animals recei- g normal rat serum. Serological examination of oncentrated and concentrated urine specimens ob- ned from all rats failed to reveal pancreas-speci- antigens. Pancreatitis seems to result from the lux of solutions carrying trypsinogen activators m the duodenum into the ducts at a time when creatic secretion is enhanced by intestinal hor- es. Pancreatic damage results from passage of activated enzymes across the acinar and ductular thelium into the interstitial tissue. The verity of the pancreatitis is augmented when im- e mechanisms are superimposed.

97 FAMILIAL CHRONIC PANCREATITIS ASSOCIATED WITH PANCREATIC LITHIASIS. *(E.)* Sato, Saitoh, Y. (Tohoku Univ. Sch. Med., Sendai, an). *Am. J. Surg.* 127(5):511-517, 1974.

eport is presented of 3 sisters, aged 11, 20, and yr, who had pancreatic lithiasis. Pancreatic hiasis in each patient was confirmed at operation was favorably treated by side-to-side pancreatico- unostomy. The symptoms and the histologic features the pancreas in these patients were similar to se of the usual form of chronic pancreatitis, but mechanism of occurrence of the disease on a fa- ial basis could not be identified. The calcifi- ions observed in these 3 cases did not differ in e from those in patients with nonhereditary di- se. No abnormalities were detected in urinary no acids, parathyroid function, or postheparin olytic activity.

8 CHRONIC PANCREATITIS IN ENGLAND: A CHANGING PICTURE? *(E.)* James, O.; Agnew, E.; Bouchier, I. A. D. (Roy. Free Hosp., London, land). *Br. Med. J.* 2(5909):34-38, 1974.

eview is presented of 107 patients with chronic creatitis from the London area seen between 1968 1973. They comprised 30 with calcific pancrea- is and 77 with chronic or chronic relapsing pancreatitis without calcification. The commonest clinical features were pain, diabetes, malabsorption, and peptic ulcer. Alcohol was a probable etiology in nearly half the cases, a different finding from those of previous surveys and possibly associated with the increased consumption of alcohol in England in the last 20 yr. Biliary tract disease was found in less than 20% of the patients. This study confirms the existence of a small but well-defined group of patients with chronic painless pancreatic disease whose etiology is obscure and in whom malabsorption and diabetes are the principal complaints. There was also a definite association between chronic pancreatitis and duodenal ulcer as 16 patients had both conditions.

4699 ACUTE PANCREATITIS WITH HYPERLIPEMIA: EVIDENCE FOR A PERSISTENT DEFECT IN LIPID METABOLISM. *(E.)* Cameron, J. L.; Capuzzi, D. M.; Zudema, G. D.; Margolis, S. (Johns Hopkins Univ., Sch. Med., Baltimore, Md.). *Amer. J. Med.* 56(4):482-487, 1974.

Lipid metabolism was studied in 22 patients (17 men and 5 women with an average age of 42 yr) with acute pancreatitis and hyperlipemia during a quiescent period. Pancreatitis was attributed to excessive alcohol intake in 21 of these patients. Persistent fasting hypertriglyceridemia was found in 16 and abnormal lipoprotein electrophoretic patterns in 17. In addition, response to a lipid load (250 g corn oil) was abnormal; in 20 of the 22 patients triglyceride levels rose above 500 mg/100 ml and in 10, above 1000 mg/100 ml. The persistence of lipid abnormalities in these patients indicates that such abnormalities are not secondary to acute pancreatitis. The possibility that hypertriglyceridemia has an intermediate role in the pathogenesis of pancreatitis is suggested by abdominal pain developing in 2 patients after their serum triglyceride levels rose above 2500 mg/100 ml. If triglyceride abnormalities play an intermediary role in the development of pancreatitis in a large percentage of alcoholics, as appears likely, monitoring of serum triglyceride levels may offer an approach to the prevention of acute pancreatitis in these patients.

4700 COLONIC NECROSIS COMPLICATING POSTOPERATIVE PANCREATITIS. *(E.)* Katz, P.; Dorman, M. J.; Aufses, Jr., A. H. (Long Island Jewish-Hillside Med. Ctr., New Hyde Park, N.Y.). *Ann. Surg.* 179(4):403-405, 1974.

A 48-yr-old woman underwent cholecystectomy and common duct exploration for chronic cholecystitis, cholelithiasis, and choledocholithiasis. After removal of the stones, there was still no passage of dye into the duodenum and a duodenotomy was performed but was closed since no obstruction was found. On the 2nd postoperative day the patient developed severe abdominal pain, signs of progressive peritonitis, fever, shock and increased serum amylase levels. Abdominal x-ray 12 days later showed mottled air in the mid-abdomen. Laparotomy on the 16th postoperative day revealed a large pancreatic abscess and peritonitis with multiple abscesses including a large pelvic abscess. In the upper portion of the left lumbar gutter, a large abscess surrounded the descending colon in which stool and a piece of necrotic colon were lying free. The abscesses were drained and a colostomy performed in the distal transverse colon. The patient improved on massive doses of antibiotics, fluids, and hyperalimentation until 23 days after surgery when she had a massive retroperitoneal hemorrhage. The next day old blood drained from the colostomy and from all drain sites, after which the patient continued to improve. A sinogram taken at discharge demonstrated a colocutaneous fistula with a sinus tract extending to the left subphrenic space. A subsequent fistulogram revealed closure of the subphrenic tract but an extension to the right side of the pelvis; this extension also gradually healed. The patient was readmitted 9 months later for resection of the fistula and reanastomosis of the colon. Two months later the colostomy was closed and the patient is now well. Hypaque enema may help establish the diagnosis of colonic necrosis. Colostomy and wide drainage of the necrotic area is recommended for prevention of sepsis and/or bleeding.

LIVER AND BILIARY TRACT

4711 DEFECTIVE BILIARY EXCRETION OF COPPER IN WILSON'S DISEASE. *(E.)* Frommer, D. J. (Roy. Free Hosp., London, England). *Gut* 15(2):125-129, 1974.

The biliary excretion of copper was measured in 8 patients with Wilson's disease (3 untreated, with hepatic dysfunction) and 10 control subjects (3 with hepatic dysfunction). The duodenum was perfused with an amino acid solution containing a nonabsorbed marker, $^{51}CrCl_3$, and the juice was aspirated from the duodeno-jejunal junction. The mean concentration of copper in the duodenal aspirate in Wilson's disease was significantly lower than in the control group. The mean biliary copper excretion rate in Wilson's disease (8.6 ± 0.8 μg/20 min (SEM)) was also significantly below that of the control group (16.4 ± 0.8 μg/20 min). The presence of liver dysfunction made no significant difference in the excretion rates in either group of patients. The results suggest that the accumulation of copper in Wilson's disease is due to the inability of the liver to excrete copper into the bile in adequate amounts.

4712 SPONTANEOUS RUPTURE OF THE LIVER IN PATIENT USING CONTRACEPTIVE PILLS. *(E.)* Frederick, W. C.; Howard, R. G.; Spatola, S. (St. Vincent's Med.

r., Richmond, Staten Island, N.Y.). *Arch. Surg.*
3(1):93-95, 1974.

sruption of the right lobe of the liver with mas-
ve hemorrhage in a young woman taking oral contra-
ptives was successfully treated by right hepatolo-
ctomy. Postoperative complications included a
bdiaphragmatic abscess which had to be drained and
persistent biliary fistula that closed 4 months af-
r hepatectomy. The patient is now asymptomatic 2
after surgery, and repeated liver scans show pro-
essive regeneration of the liver mass. Pathologic
amination of the resected liver revealed evidence
hepatic vein thrombosis, necrosis, and hemorrhage.
evidence was found of acute congestion and hemor-
age consistent with Chiari's syndrome. In the
sence of any history of trauma, and in view of
e pathologic findings, it is suggested that an
sociation exists between the development of this
ndition and the use of oral contraceptives.

13 A STEREOLOGICAL STUDY OF INTRAHEPATIC BILE DUCTS. 4. CONGENITAL HEPATIC FIBROSIS.

.) Jorgensen, M. (Gentofte Health Inst., Copen-
gen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*]
(1):21-29, 1974.

e intrahepatic biliary system in congenital hepatic
prosis has been evaluated by means of stereological
amination and reconstructions of 10 liver specimens
om 8 patients. The ductal system consisted of a
aracteristic mixture of different ductal shapes in-
uding very flattened, plate-like ducts. These ducts
re arranged in irregular networks which were
ually organized in separate planes and which often
mpletely or incompletely surrounded blood vessels.
change with age was found in the ductal anatomy.
e biliary system is fundamentally identical in
ngenital hepatic fibrosis and in infantile poly-
stic disease. It is not possible to determine
om the present study whether or not there may be a
nor systematic difference between the ductal le-
ons found in these 2 diseases. The flattened duc-
l shape is considered to result from a failure in
e embryological development of the biliary system.

14 A BIOCHEMICAL ABNORMALITY IN CEREBROTENDINOUS XANTHOMATOSIS. IMPAIRMENT OF BILE
ID BIOSYNTHESIS ASSOCIATED WITH INCOMPLETE DEGRA-
TION OF THE CHOLESTEROL SIDE CHAIN.

(E.)
toguchi, T.; Salen, G.; Tint, G. S.; Mosbach, E.
(Public Health Res. Inst., New York, N.Y.). *J.*
in. Invest. 53(5):1393-1401, 1974.

le acid precursors were sought in bile and feces
3 subjects with cerebrotendinous xanthomatosis.
er 10% of the total sterols excreted in bile and
ces consisted of compounds more polar than chlo-
terol. Chromatographic analysis of the polar
actions in conjunction with gas-liquid chromato-
aphy-mass spectrometry indicated 2 major constit-
nts, 5β-cholestane-3α,7α,12α,25-tetrol and 5β-
olestane-3α,7α,12α,24ξ,25-pentol. After i.v. in-
ction of (4-^{14}C)cholesterol, both bile alcohols
re radioactive, proving that they were derived
om cholesterol. The accumulation of alcohols
droxylated at C-25 and C-24,25 suggests that decreased bile acid synthesis in cerebrotendinous xanthomatosis results from impaired oxidation of the cholesterol side chain. The abnormally high activities of the rate-controlling enzymes of bile acid synthesis can then be ascribed to failure of the bile alcohols to exert negative feedback control on these enzymes either due to the bile alcohols not being absorbed or because they lack the structural requirements to interact with the hepatic regulatory system. Thus, patients with cerebrotendinous xanthomatosis synthesize insufficient quantities of bile acids to maintain the pool size required for normal feedback control of bile acid and cholesterol production. The demonstration of substantial amounts of the tetrol and the pentol and in the feces suggests that the patients lack the enzyme to catalyze the further transformation of the pentol to cholic acid. In any case, the finding of 25-hydroxylated bile alcohols, and the lack of 26-hydroxylated intermediates, may have important implications in the biochemical pathway of bile acid synthesis.

4715 CRYOGLOBULINS IN ACUTE AND CHRONIC LIVER DISEASES.

(E.) Florin-Christensen, A.; Roux, M. E. B.; Arana, R. M. (Ctr. Med. Ed. Clin. Invest., Buenos Aires, Argentina). *Clin. Exp. Immunol.* 16(4):599-605, 1974.

Cryoglobulins were detected in the sera of a group of 13 patients with acute viral hepatitis and in those of a group of 12 patients with chronic liver diseases, including 7 cases of active chronic hepatitis, 3 cases of primary biliary cirrhosis, and 2 cases of cryptogenic cirrhosis. Concentrations of cryoglobulin in the serum ranged from 0.2 to 1 mg/ml. Cryoglobulin preparations from the viral hepatitis patients were partially soluble at 37°C and completely soluble at 40 C while those from chronic liver disease patients were poorly soluble at 37 C and only moderately more soluble at 40 C. Most of the preparations contained mixtures of IgM and IgG or of IgM, IgG, and IgA. Some, however, consisted of single-class immunoglobulins, including IgM(κ), IgG(κ), and IgG(λ). Unusual components were also found. For example, α_1-fetoprotein was present in 4 cryoprecipitates: in 2 of these, as the single constituent and in 2 others, associated with immunoglobulins. In another example, hepatitis-associated antigen coexisted with IgM, IgG, and α_1-fetoprotein. Autoantibody activities in the different cryoglobulins were found against human γ-globulin, nuclear, smooth muscle, and mitochondrial antigens. In one case, the IgM(κ) of the cryoprecipitate had antibody activity against α_1-fetoprotein, and α_1-fetoprotein was also present in the cryoprecipitate, suggesting immuno-complex formation. Autoantibodies were also studied in the patients' sera, and, depending on the patient, were found against γ-globulin, nuclei, DNA, single stranded DNA, saline-soluble calf thymus extract, smooth muscle, non-organ-specific cytoplasm, gastric parietal cell cytoplasm, mitochondria, and α_1-fetoprotein.

4716 UNUSUAL PATTERN OF HEPATIC ALKALINE PHOSPHATASE ACTIVITY AND RENAL CARCONOMA.

(E.) Axelsson, U.; Hagerstrand, I.; Zettervall, O. (Dept. Internal Med., Univ. Lund, Sweden). *Acta Med. Scand.* 195(3):223-225, 1974.

Two patients, a 35-yr-old woman and a 54-yr-old man, had renal carcinomas associated with hepatic dysfunction in the absence of hepatic metastases. Moderately elevated serum alkaline phosphatase activity was found. Liver biopsy specimens disclosed the morphology was normal, but the abnormal localization of alkaline phosphatase activity was found adjacent to the canaliculi in the entire hepatic lobules. One patient had strong acid phosphatase activity in the hepatocyte lysosomes, while β-glucuronidase activity was weak. These finding were reversed in the other patient. Serum alkaline phosphatase and platelet levels normalized after extirpation of the tumor. It is concluded that the canalicular phosphatase activity is in some way induced by a humoral tumor agent. The agent produced by the tumor cells might enter hepatocytes through endocytosis and be at least partly digested by acid hydrolases, and metabolites might be secreted into the bile demanding canalicular alkaline phosphatase activity. It should be realized that liver function disorders may be a paraneoplastic manifestation and are not necessarily symptoms of liver metastasis.

4717 CONGENITAL HEPATIC FIBROSIS. TWO CASES SIMULATING HEPATIC CIRRHOSIS.

(E.) Campana, H. A.; Park, Y. S.; Gourgoutis, G. D. (VA Ctr., Dayton, Ohio). *Am. J. Dig. Dis.* 19(4): 325-333, 1974.

Congenital hepatic fibrosis was detected in a 10 yr-old-boy with hepatosplenomegaly and leukopenia and in a 45-yr-old male with hepatomegaly. Bleeding attributable to esophageal varices occurred several years after the original findings in both patients. This was treated by elective portasystemic shunts. Several factors were used in differentiating the congenital hepatic fibrosis from cirrhosis of the liver. In both patients, the preshunt liver function tests were essentially normal, but essentially normal or borderline liver function tests have been reported for latent or posthepatic cirrhosis as well. Liver scans showed homogeneous uptake of ^{198}Au in these patients, suggestive of congenital hepatic fibrosis. Gross morphology of the livers at laparotomy was indistinguishable from that of cirrhosis. Liver wedge biopsies revealed portal and interlobular fibrosis and biliary duct hyperplasia, simulating cirrhosis, but in neither case was there evidence of sequelae of liver-cell necrosis such as pseudolobulation, replacement fibrosis, or hepatocyte regeneration which would have been present in cirrhosis. Other biopsy findings useful in the differentiation included mature bile duct proliferation, absence of significant intraportal or interlobular inflammatory infiltrate, and small or hypoplastic distal portal vein branches. No progression of the disease was noted on liver biopsy repeated 8 yr later, a significant difference from the expected findings in cirrhosis cases. Hepatic vein catheterization and portal venography in the adult patient indicated intrahepatic presinusoidal block, while in cirrhosis of the liver, para- or post-sinusoidal blocks are more typical. Neither patient had jaundice, ascites, or polycystic kidneys. Each case appeared sporadic.

4718 MORPHOLOGIC STUDIES ON SECONDARY PHOSPHOLIPIDOSIS IN HUMAN LIVER.

(E.) De La Iglesia, F. A.; Feuer, G.; Takada, A.; Matsuda, Y. (Warner Lambert Res. Inst., Toronto, Canada). *Lab. Invest.* 30:4):539-549, 1974.

Liver biopsy specimens were studied from 5 Japanese patients (4 females and 1 male, aged 42-60 yr) who showed protracted hepatic involvement and characteristic clinical manifestations of slight fever, anorexia, general malaise, and upper respiratory tract involvement. Light microscopic investigations of paraffin-embedded liver tissue materials revealed a foamy cytoplasmic appearance of hepatocytes and moderate bile duct proliferation with accumulation of inflammatory cells in the portal spaces. Dense dark bodies were found in semithick sections as revealed by differential interference contrast microscopy. All cell types seen in the liver parenchyma reflected this change. Ultrastructural features consisted of dark bodies, intracytoplasmic inclusions, and altered mitochondria in the hepatocytes. The dense bodies represented secondary lysosomes, with typical onion-like configuration of material resembling myelin. The development of these liver changes has been attributed to the long term (at least 6 months) administration of 4, 4'-bis-(β-diethylaminoethoxy)-α,β-diethyldiphenylethane, (Coralgil), a coronary vasodilating agent. These results, coupled with animal studies, suggest that the drug was probably responsible for the impairment of the hepatic phospholipid synthesis. The effects can be considered either a secondary lysosomal response with subsequent alteration of the rate of phospholipid disposition, or a direct interference with phospholipid metabolism leading to either aberrant binding or formation of foreign phospholipids which cannot be eliminated through normal pathways.

4719 LONG-TERM CHELATION THERAPY IN THALASSAEMIA MAJOR: EFFECT ON LIVER IRON CONCENTRATION, LIVER HISTOLOGY, AND CLINICAL PROGRESS.

(E.) Barry, M.; Flynn, D. M.; Letsky, E. A.; Risdon, R. A. (Royal Free Hosp., London, England). *Br. Med. J.* 2(5909):16-20, 1974.

A trial of continuous chelation therapy was conducted on 9 children with homozygous thalassemia for a period of time ranging from 5.2 to 6.3 yr. Nine other thalassemic children, used as controls, were not treated with chelators. All 18 patients were transfused every 4-8 weeks to keep the hemoglobin concentration between 8.0 and 15.0 g/100ml. The chelator-treated patients received desferrioxamine mesylate (0.5 g in 2 ml water, i.m., 6 days/week) and diethylenetriamine penta-acetate (2 g, i.v. with each unit of blood). The latter drug was changed to desferrioxamine in 4 cases. The difference in mean liver iron concentration between the treated and untreated groups at the start of the study was not significant. In both groups the liver iron concentration increased with the amount of blood transfused, but the rise was much greater in the controls. Similarly, fibrosis levels at the start of the trial were not significantly different between the groups, but, by the end of the trial, there was progressive fibrosis in the controls and no significant change in the chelator-treated group. No major clinical differences were noted between the 2 groups, perhaps because both groups included several older children who were heavily loaded with iron at the start of the trial. Among the younger patients, however, puberty was delayed in 4 of 5 controls but in only 1 of 4 chelator-treated children. Prepubertal growth rate was significantly greater in the chelator-treated patients than in the controls.

4720 PRIMARY LEIOMYOSARCOMA OF THE LIVER.

(E.) Fong, J. A.; Ruebner, B. H. (Univ. California Sch. Med., Davis). *Hum. Pathol.* 5(1):115-119, 1974.

Leiomyosarcoma was diagnosed from a liver biopsy taken from a 62-yr-old man who presented with abdominal swelling of 1 month's duration and a history of abdominal pain and a weight loss of 20 pounds dating back 1 yr. Liver scanning with ^{198}Au revealed that about 60% of the liver had been replaced by nodules of nonfunctioning tissue. Although no specific therapy was administered, the patient survived for 20 months after the diagnosis had been established. At autopsy, 95% of the liver had been replaced by coalescing tumor nodules ranging in size from 2-15 cm. Other findings included approximately 5000 ml of ascitic fluid and metastases in the lungs, pancreas, peritoneum, thyroid, adrenals, and kidneys. No evidence of cirrhosis was found. This is the 8th reported case of a primary hepatic leiomyosarcoma. Since these tumors appear to follow a relatively indolent course, it is recommended that they be treated by hepatic dearterialization and infusion of 5-fluorouracil *via* the portal vein, followed by resection, if possible.

4721 ACUTE FATTY LIVER OF PREGNANCY WITH DISSEMINATED INTRAVASCULAR COAGULATION.

(E.) Holzbach, R. T. (St. Luke's Hosp., Cleveland, Ohio). *Obstet. Gynecol.* 43(5): 740-744, 1974.

A 29-yr-old female presented with epigastric pain, nausea, and vomiting following ingestion of furosemide (40 mg/day) prescribed for ankle edema and a sudden 7-lb weight gain during the 35th week of pregnancy. These symptoms, plus cephalopelvic disproportion necessitated successful termination of the pregnancy by elective cesarean section after which the patient became almost oliguric. On the 2nd postoperative day gastrointestinal bleeding was noted and was followed by fever, hyperbilirubinemia, and increased serum alkaline phosphatase and SGOT values. Her symptoms paralleled those for acute fatty liver of pregnancy. A liver biopsy obtained during the resolving phase of the illness showed distension of the cytoplasm by many small vacuoles, but nuclei were normal both in appearance and in their position within the cell. These findings contrast with those observed in fatty liver associated with nutritional deficiencies or excessive alcohol intake. Laboratory evidence suggestive of an associated disseminated intravascular coagulation process included red cell morphology showing typical microangiopathic changes, a marked reduction of measured coagulation precursor substrates as well as RBC and platelets, and the identification of fibrinogen-split products in the presence of very low levels of circulating fibrinogen. It is suggested that disseminated intravascular coagulation may be important in the widespread organ abnormalities found in acute fatty liver of pregnancy. Early information as to its presence should be sought in these cases so that the intensive therapeutic regimen, including replacement therapy with fresh-frozen plasma and intermittent i.v. heparin in controlled dosages, might be started.

4722 RECURRENT JAUNDICE IN PREGNANCY. IV. QUANTITATIVE DETERMINATION OF URINARY AND BILIARY ESTROGENS, INCLUDING STUDIES IN PRURITUS GRAVIDARUM.

(E.) Adlercreutz, H.; Tikkanen, M. J.; Wichmann, K.; Svanborg, A.; Anberg, A. (Dept. Clin. Chem., Univ. Helsinki, Finland). *J. Clin. Endocrinol. Metab.* 38(1):51-57, 1974.

Estrogen metabolism in recurrent jaundice of pregnancy and pruritus gravidarum was studied by determining 12 different estrogens in bile and urine. A uniformly marked fall in the biliary concentrations of all estrogens was observed in pregnancy jaundice. This would suggest that the enterohepatic circulation of these steroids is impaired and offers an explanation for the abnormal pattern of urinary estrogens observed in the two related syndromes. The relative excretion (= percentage of total estrogens) of estriol and 16-epiestriol in urine was diminished, whereas that of their espective precursors, 16α-hydroxyestrone and 16β-hydroxyestrone was increased. Rather small or insignificant changes were seen in the urinary excretion of other estrogens. Hence the main alterations occurred in the 16-hydroxylation pathways and included decreased conversion of 16α-hydroxyestrone to estriol and of 16β-hydroxyestrone to 16-epiestriol. The primary cause of these alterations is most likely the decreased biliary excretion of estrogens with consequent impairment of their enterohepatic circulation. This is in accordance with the view that recurrent jaundice of pregnancy and pruritus gravidarum are not caused by a primary abnormality in estrogen production or metabolism in the fetoplacental unit.

4723 STUDIES OF LIPIDS AND LIPOPROTEINS IN LIVER DISEASE. *(Ger.)* Vogt, N.; Greiner, M.; Wienbeck, M.; Dolle, W.; Englhardt, A. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1330-1332, 1972.

Serum lipids and lipoproteins were separated by gel electrophoresis, stained with Schiff's reagent, and determined densitometrically on 30 patients with serum hepatitis, 27 with acute viral hepatitis, and a group of patients with chronic persistent and chronic aggressive hepatitis, cirrhosis, and acute and subacute hepatic dystrophy. Total lipids and β-lipoproteins increased while α-lipoproteins and pre-β-lipoproteins decreased in acute hepatitis. When symptoms were most severe, the pre-β- and β-lipoprotein fractions could not be separated in many cases. In one patient who developed acute hepatitis after receiving several blood transfusions, lipoprotein values were correlated with both triglyceride and transaminase values since the increase in triglycerides was associated with an increase in β-lipoproteins. A second episode of hepatitis, which occurred 25 days after onset of symptoms, was associated with a second increase in transaminase values, a decrease in α-lipoproteins, and a loss of the pre-β-lipoprotein fraction. A second patient with alcoholic hepatitis had a lipoprotein pattern characteristic of acute hepatitis but only slightly increased transaminase values. Simultaneous changes occurred in triglyceride and lipoprotein values. In a patient with diabetes mellitus who required insulin, the type IV pattern associated with diabetes disappeared during the acute stage and appeared again toward the end of the disease. No significant changes occurred in the triglyceride levels in patients with compensated and decompensated cirrhosis but, depending upon the severity of the disease, the lipoprotein pattern was similar to that found in acute hepatitis. Statistically significant decreases occurred in the α- and pre-β-lipoprotein fractions in chronic aggressive hepatitis, decompensated cirrhosis, and hepatic coma. Since cholestasis was detected in only a few cases, it can be ruled out as the cause of changes in the lipoprotein pattern of these patients.

4724 EFFECT ON THE DIURESIS OF SIMULTANEOUSLY APPLIED INFUSIONS OF HYPOTONIC LIQUID INTO THE PORTAL VEIN AND OF HYPERTONIC LIQUID INTO THE SUPERIOR VENA CAVA. AN ATTEMPT AT DEMONSTRATING THE EXISTENCE OF AN INTRAPORTAL OSMOREGULATORY SYSTEM IN MAN. *(E.)* Lindahl, F.; Lund, B.; Boas, B.; Schmidt, A. (Frederiksberg Hosp., Hellerup, Denmark). *Scand. J. Gastroenterol.* 9(2):133-136, 1974.

In order to demonstrate the existence of an intraportal osmoregulatory system in man, catheters were introduced prior to surgery, via the umbilical vein into the portal vein in 15 patients, aged 42-73 years. Of the 15 patients, 10 suffered from cholelithiasis, 2 from duodenal ulcer, and 2 from nonmetastasizing cancer of the colon. There was 1 on whom explorative coeliotomy revealed no pathological process. Renal and liver functions in all were normal. After surgery, 100 ml of a hypotonic solution was infused via the catheter and, in order to obtain isomolarity in the right atrium after mixing, the same volume of hypertonic sodium chloride was infused via the catheter in the superior vena cava. A 1.2% change in the osmolarity in the left portal vein did not bring about any significant changes in the diuresis within six 15-min periods. Each patient served as his own control and changes in the diuresis were considered relevant indicators of the effect. Therefore it was concluded that the possible existence of an intraportal osmoregulatory system could not be considered to be of any physiological significance.

4725 REYE'S SYNDROME AND HYPERAMINOACIDEMIA. *(E.)* Hilty, M. D.; Romshe, C. A.; Delamater, P. V. (Med. Coll. Georgia, Augusta). *J. Pediatr.* 84(3):362-365, 1974.

The serum amino acids have been quantitated in 16 children with Reye's syndrome, 2 children with hepatitis and hepatic coma and 5 children with salicylism. The 5 children with salicylism had had viral illnesses and had been treated with acetylsalicylic acid (117 to 295 mg/kg/day for 24 to 144 hr) and at admission they were acidotic, semicomatose, hyperpneic, and had serum salicylate concentrations from 38-80 mg/100 ml. Liver functions in the children with hepatitis and hepatic coma were abnormal and remained so for at least 2 months. Hyperaminoacidemia was present in all Reye's syndrome patients with the most consistent and largest increases occurring with glutamine, alanine, α-amino-N-butyrate, and lysine. Significant differences in the concentrations of glycine, alanine, valine, leucine, ornithine, and lysine were noted between patients who survived and those who did not survive. Serum amino acid concentrations were normal in all children with salicylism and in 1 child with hepatitis and hepatic coma. In the other child with hepatitis, glutamic acid, alanine, methionine, and ornithine were only moderately elevated. In Reye's syndrome patients, SGOT values ranged from 64 to 1,420 U/ml and SGPT from 125 to 2,240 U/ml. In the salicylism patients, increased blood ammonia and serum transaminase were noted unexpectedly, and thought to result from excessive acetylsalicylic acid ingestion. These results indicate that the amino acid pattern of Reye's syndrome reflects a deficiency of ornithine transcarbamylase which may be secondary to injury of hepatic mitochondria. It is felt that serum amino acid analysis may help distinguish Reye's syndrome from hepatitis with hepatic coma and from severe salicylism.

4726 NONMETASTATIC HEPATOMEGALY AND LIVER MALFUNCTION ASSOCIATED WITH RENAL CANCER. *(Fr.)* Gadrat, J. (no affil.). *Bull. Acad. Natl. Med.* 156(16/17):499-510, 1972.

Case reports are presented for 2 women with primary nephroepitheliomas who also had hepatomegaly and evidence of abnormal liver function although no evidence of hepatic metastases was found. A 48-yr-old woman presented with hepatomegaly, fever, and eosinophilia of unknown origin. Total bilirubin, serum alkaline phosphatase activities, and the BSP retention time were increased, but liver scans showed no evidence of a tumor and a liver biopsy revealed localized nonspecific granulomatosis in the portal spaces and entire parenchyma. An i.v. pyelogram was normal and tests for collagen diseases and parasites were negative. The patient was discharged without a diagnosis after her fever had been controlled with indomethacin. She was hospitalized again 4 months later with splenomegaly, enlargement of the right submaxillary gland, and persistent eosinophilia. Microvesicular steatosis was found in the liver, and pathological examination of the right submaxillary gland revealed a massive metastasis from an epithelioma which was probably renal in origin. Evidence of a renal tumor was detected on a second i.v. pyelogram along with an increase in the size of a lymph node situated on the level of the 2nd lumbar vertebra, suggesting the presence of another metastasis. The patient died a few weeks later, but no autopsy was performed. A 28-yr-old woman presented with abdominal pain which responded to antispasmodics, hepatomegaly, anemia, and an increased erythrocyte sedimentation rate. Three months later a mass was palpated below the liver and radiological examinations revealed compression of the duodenum and gallbladder. Other findings included hypergammaglobulinemia with a significant increase in γ_M-globulin typical of cirrhosis and increases in serum alkaline phosphatase and BSP retention times. Evidence for a renal tumor was obtained from uretomography and arteriography of the celiac trunk, superior mesenteric, and right renal arteries. At surgery a clear-cell epithelioma was removed *en bloc* with the right kidney, and no metastases were found in the liver. The liver returned to its normal size a few weeks later, and alkaline phosphatase activities and BSP retention times gradually normalized.

Hyperbilirubinemic States

4759 TETRACYCLINE HEPATOTOXICITY IN THE DIFFERENTIAL DIAGNOSIS OF POSTOPERATIVE JAUNDICE.

(E.) Lloyd-Still, J. D.; Grand, R. J.; Vawter, G. F. (Harvard Med. Sch., Boston, Mass.). *J. Pediatr.* 84(3):366-370, 1974.

Hepatotoxicity due to tetracycline occurred in 3 females (aged 2-10 yr) with obstructive uropathies. Differential diagnosis in these children included fulminant viral hepatitis or halothane toxicity with hepatic necrosis, severe bacterial or viral septicemia, Reye's syndrome, and other causes of postoperative jaundice. The clinical and histological features strongly favored tetracycline hepatotoxicity in that all 3 developed nausea, vomiting, jaundice, progressive lethargy, coma and fine fatty infiltration of the liver a few days after the i.v. administration of the drug. No histological features of halothane toxicity or viral hepatitis was present. Some impairment of renal function was present in all patients. Autopsy findings on the 2 who died showed fatty infiltration of the liver and disseminated candidiasis. Recovery occurred in 1 patient after the use of tetracycline was discontinued; liver biopsy confirmed the presence of fatty infiltration. In 2 cases the history showed episodes of hypotension that could have caused the extensive renal tubular damage but there was also evidence of cytoplasmic vacuolization in all tubules. The etiology of the hyperglycemia in 2 cases was not known. These findings demonstrate the dangers of administering tetracycline i.v. to children with impaired renal function, and differentiate tetracycline-induced hepatic injury from that due to halothane.

4760 EFFECT OF PHENOBARBITONE ON PLASMA [14C]BILIRUBIN CLEARANCE IN PATEINTS WITH UNCONJUGATED HYPERBILIRUBINEMIA.

(E.) Black, M.; Fevery, J.; Parker, D.; Jacobson, J.; Billing, B. H.; Carson, E. R. (Royal Free Hosp., London, England). *Clin. Sci. Mol. Med.* 46(1): 1-17, 1974.

The clearance of a tracer dose of [^{14}C]bilirubin from the plasma was studied in 12 patients with Gilbert's syndrome (2 females and 10 males, aged 16-57 yr), 4 patients with congenital non-hemolytic jaundice (1 female and 3 males, aged 8-14 yr), 1 patient with hemolytic jaundice (male, aged 23 yr), and 4 normal subjects (all males, aged 29-32 yr). Clearance was significantly impaired in patients with Gilbert's syndrome and in those with congenital non-hemolytic jaundice when compared with normal controls, but was normal in the patient with hemolytic jaundice. Treatment with phenobarbital (180 mg/day for 2 weeks) lowered the plasma bilirubin concentration and improved all indices of plasma clearance of the isotope in patients with Gilbert's syndrome, so that their values became indistinguishable from those of the controls. The improvement in plasma [^{14}C]bilirubin clearance in these patients was associated with modest increases in hepatic bilirubin glucuronyl transferase in some subjects. Phenobarbital treatment improved plasma bilirubin concentrations and plasma [^{14}C]bilirubin clearance in patients with congenital non-hemolytic jaundice, so that they resembled those seen in patients with untreated Gilbert's syndrome. Despite this improvement, hepatic bilirubin glucuronyl transferase activity remained undetectable. These results compare well with the hypothesis that Gilbert's syndrome is a manifestation of a relative deficiency of hepatic bilirubin glucuronyl transferase, and differs from congenital non-hemolytic jaundice only in severity.

4761 INCREASED GLUCURONIDATION OF BILIRUBIN IN MAN AND RAT BY ADMINISTRATION OF ANTIPYRINE (PHENAZONE).

(E.) Orme, M. L'E.: Davies, L.; Breckenridge, A. (Royal Postgrad. Med. Sch., London, England). *Clin. Sci. Mol. Med.* 46(4):511-518, 1974.

Antipyrine (600 mg/day for 6 weeks) was administered to 6 male patients (aged 17-35 yr) with Gilbert's syndrome. This treatment caused a significant fall in both total and unconjugated serum bilirubin concentrations with none of the side effects associated with phenobarbital therapy. The maximum reduction in serum bilirubin concentration was achieved by 2 weeks and, after this time, the level remained relatively constant. When male Wistar rats were given twice daily i.p. injections of antipyrine (80 or 240 mg/kg) for 3-1/2 days, a significant increase was observed in the apparent maximal velocity for the glucuronidation of bilirubin by liver microsomal preparations, as determined by varying the concentration of either uridine diphosphate glucuronic acid or bilirubin in the tests. There was no significant difference between the apparent maximal velocity values attained with the 2 different doses of antipyrine. Neither the microsomal protein content nor the apparent affinity constant was altered in these studies with antipyrine. Comparable administration of phenobarbital (80 mg/kg) caused significant increase in the microsomal protein content, but no significant change in the values for the apparent maximal velocity or apparent affinity constant for the glucuronidation of bilirubin with varying concentrations of uridine diphosphate glucuronic acid and bilirubin. Applied to the situation in humans, these results suggest that the fall in serum unconjugated bilirubin after treatment with phenobarbital may not be due to increased activity of bilirubin-glucuronosyltransferase. Phenobarbital may cause an increase in liver blood flow, bile flow, or organic anion hepatic binding protein, all perhaps contributing to serum bilirubin changes. Antipyrine may act by causing a specific increase in enzyme activity, and in patients with low bilirubin-glucuronosyltransferase activity it would be more acceptable for therapy than phenobarbital.

4762 HEPATIC BILIRUBIN GLUCURONIDATION IN NEONATES WITH UNCONJUGATED HYPERBILI-

RUBINEMIA AND CONGENITAL GASTROINTESTINAL OBSTRUCTION. *(E.)* Felsher, B. F.; Carpio, N. M.; Woolley, M. M.; Asch, M. J. (Univ. Southern California Sch. Med., Los Angeles). *J. Lab. Clin. Med.* 83(1):90-96, 1974.

Hepatic bilirubin uridine diphosphate glucuronyl transferase activity was assayed in surgical liver biopsies from 10 icteric and 7 anicteric neonates who underwent laparotomy for congenital gastrointestinal obstruction, and from 6 neonates with obstructive jaundice unassociated with gastrointestinal obstruction. In the icteric group (5 males and 5 females, aged 2 to 41 days at surgery), the serum bilirubin was predominantly unconjugated and its concentration ranged from 2.4 to 15.9 mg/100 ml, while the uridine diphosphate glucuronyl transferase activity ranged from 0 to 180 μg of bilirubin conjugated/hr/g liver. Pyloric stenosis was present in 6 patients, malrotation in 2, and duodenal atresia with malrotation in 2. The anicteric group (5 males and 2 females, aged 19-71 days), all with pyloric stenosis, had serum bilirubin concentrations of only 0.5 to 1.7 mg/100 ml, while their uridine diphosphate glucuronyl transferase activities showed a range of 520 to 800 μg bilirubin conjugated/hr/g liver, which was within or slightly below the previously determined normal range in adults. The enzymic activity for the 6 neonates (aged 14 to 85 days) with obstructive jaundice unassociated with gastrointestinal obstruction was normal (780 to 1840 μg bilirubin conjugated/hr/g liver). The results thus showed that hepatic bilirubin uridine diphosphate glucuronyl transferase activity in neonates with unconjugated hyperbilirubinemia and gastrointestinal obstruction is markedly and uniformly decreased compared with anicteric neonates with pyloric obstruction and neonates with obstructive jaundice. The unconjugated hyperbilirubinemia associated with congenital gastrointestinal obstruction likely results from caloric deprivation superimposed on an underlying deficiency of hepatic uridine diphosphate glucuronyl transferase activity.

4763 UNCONJUGATED HYPERBILIRUBINEMIA IN ACHALASIA. *(E.)* Fevery, J.; Heirwegh, K. P. M.; De Groote, J. (St. Rafael Univ. Hosp., Louvain, Belgium). *Gut* 15(2): 121-124, 1974.

Moderate unconjugated hyperbilirubinemia was observed in 2 patients (1 male and 1 female, aged 44 and 22 yr, resp.) with achalasia. Liver biopsy showed that the hepatic digitonin-activated bilirubin uridine diphosphate glucuronyl transferase activity was decreased in both patients and they were considered, therefore, to have Gilbert's syndrome. The achalasia seemed only to have functioned by inducing caloric restriction, thus causing the hyperbilirubinemia known to be associated with fasting. The hyperbilirubinemia decreased after pneumatic dilatation of the gastroesophageal sphincter to permit a normal amount of food intake. This situation is comparable to the jaundice found in neonates with pyloric stenosis or other types of obstruction of the upper gastrointestinal tract. The mechanism for fasting-induced type hyperbilirubinemia appears complex.

4764 EFFECT OF SOME ANTIINFLAMMATORY AGENTS ON EXPERIMENTAL HYPERBILIRUBINEMIA. *(Rus.)* Pidemskii, E. L.; Vakhrusheva, L. G.; Mardanova, L. G. (Natl. Sci. Inst., Perm Univ., USSR). *Patol. Fiziol. Eksp. Ter.* (3):39-42, 1973.

The effects of antiinflammatory agents was studied on hyperbilirubinemia induced in Wistar rats by administration of carbon tetrachloride (0.4 mg/kg p.o. for 3 successive days) or by ligation of the bile ducts. Starting on the 2nd day carbon tetrachloride was given, rats received prednisolone (1 mg/kg), nifenazone (10 mg/kg), phenylbutazone (30 mg/kg), or anthradione (50 mg/kg) daily p.o. in 2% starch suspension. All of these agents prevented the development of hyperbilirubinemia in carbon tetrachloride-treated rats. Blood bilirubin levels were even lower in treated rats than in intact controls. Since no bilirubin was ever excreted in the urine or treated rats or controls, these drugs do not act by increasing urinary bilirubin excretion. The same doses of antiinflammatory agents were administered to rats immediately after bile duct ligation. All drugs prevented hyperbilirubin in bile-ligated rats. In these animals, a direct relation was found between blood bilirubin levels and urinary bilirubin excretion. Although prednisolone and nifenazone increased diuresis, they did not stimulate bilirubin excretion in the urine. Phenylbutazone and anthradione had no appreciable effect on diuresis. Thus, none of these agents acts by increasing urinary bilirubin excretion in the animal models studied. In bile-ligated rats the possibility that bilirubin might be excreted in the stools is ruled out. It is suggested that prednisolone, nifenazone, phenylbutazone, and anthradione prevent hyperbilirubinemia by inhibiting bilirubin synthesis in cells of the reticuloendothelial system.

4765 UNIQUE RELATIONSHIP BETWEEN BILIRUBIN TURNOVER AND BILIRUBIN CLEARANCE IN TYPE I CONGENITAL NONHEMOLYTIC JAUNDICE (CNJ). *(E.)* Berk, P. G.; Scharschmidt, B. F.; Waggoner, J. G.; White, S. C. (no affil.). *J. CLin. Invest.* 53(6): 6a, 1974.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

4767 JAUNDICE AND RIFAMPICIN: CRITICAL STUDY. *(Fr.)* Nebout, T.; Dhumeaux, D.; Berthelot, P. (Henri Mondor Hosp., Creteil, France). *Nouv. Presse Med.* 3(12):733-736, 1974.

A questionnaire sent to 22 hospital centers and sanitoria showed that between January 1968 and March 1970, 86 patients developed jaundice during rifampicin therapy. An analysis was made of clinical findings of 70 patients (48 men and 22 women) for whom adequate clinical and histological information was available. Of these 70 patients, 30 were probably chronic alcoholics, 2 had cirrhosis confirmed by liver biopsy, and 5 others probably had cirrhosis. Patients were classified into 3 groups, depending on whether rifampicin was an unlikely cause of jaundice (24 patients), a possible cause (39 patients), or a probable cause (7 patients). In 5 of the 7 patients (6 women and 1 man) whose jaundice was probably caused by rifampicin, the repeated administration of rifampicin caused a recurrence of hyperbilirubinemia. The proportion of women in this group was significantly higher than in the group whose jaundice was not likely to be caused by rifampicin (23 men and 1 woman). The test of Mann and Whitney was used to compare differences in the period between institution of therapy and development of jaundice, duration of jaundice, maximum serum bilirubin concentration, maximum SGPT activity, and rifampicin dosage for these 3 groups of patients. No significant differences were found for any of the parameters studied between the group in which rifampicin was an unlikely cause of jaundice and that in which it was the probable cause.

4768 DETECTING THE EFFECTS OF AN ASSOCIATION OF RIFAMPICIN AND ISONIAZIDE ON THE HUMAN LIVER. *(Fr.)* Plomteux, G.; Heusghem, C.; Ferdinande, R.; Lecoq, A.; Winandy, A.; Parmentier, J. C. (Lab. Med. Chem. Toxicol., Liege, Belgium). *Nouv. Presse Med.* 3(12):727-732, 1974.

Liver function tests were performed systematically on 20 patients with extrapulmonary tuberculosis receiving 200 mg/day of isoniazid and/or 450 mg/day of rifampicin and on 30 patients with pulmonary tuberculosis receiving 300 mg/day of isoniazid and 450 mg/day of rifampicin. Of the 20 patients with extrapulmonary tuberculosis, 18 initially had no abnormalities in liver function and 16 never developed any. During administration of isoniazid alone 1 patient developed a slight temporary increase in serum γ-glutamyl transpeptidase and another had SGPT values which increased to 70 mIU and normalized after 10 weeks. No exacerbations occurred in the 2 patients who had evidence of abnormal liver function before institution of therapy. Of the 30 patients with pulmonary tuberculosis, 25 had no liver function disorders before institution of therapy and 13 never did develop any. Only 1 patient with initially normal findings developed large increases in SGOT and SGPT values shortly after institution of therapy, but liver function tests normalized rapidly despite continuation of therapy. Of the 5 patients with pulmonary tuberculosis who had liver function abnormalities initially, 3 with slight dysfunction improved and 1 had mild but permanent dysfunction over a 20-wk observation period. After rapid improvement initially, an 80-yr-old alcoholic developed jaundice which was rapidly fatal although tests for membrane permeability were only slightly abnormal. In addition to cirrhosis, this patient had cholelithiasis and biliary tuberculosis which would favor the development of jaundice. Since the period between institution of therapy and development of jaundice was long (81 days), it is unlikely that death resulted from a direct hepatotoxic effect. Thus, these findings showed that liver function abnormalities were significantly more common among patients with pulmonary tuberculosis than among those with extrapulmonary tuberculosis during administration of isoniazid and rifampicin.

Acute Viral Hepatitis

4772 SERUM CHOLESTEROL ESTERIFICATION IN HUMAN LIVER-DISEASE: ROLE OF LECITHIN-CHOLESTEROL ACYLTRANSFERASE AND CHOLESTEROL ESTER HYDROLASE. *(E.)* Simon, J. B.; Kepkay, D. L.; Poon, R. (Dept. Med., Queen's Univ., Kingston, Ontario, Canada). *Gastroenterology* 66(4):539-547, 1974.

The net cholesterol-esterifying activity and activity of lecithin-cholesterol acyltransferase (LCAT) were simultaneously assayed in the sera of 25 patients with parenchymal liver disease, the former being measured using a colorimetric method and the latter being assessed using a ^{14}C-isotopic assay. There was close agreement between the two esterification rates, and the mean values were similar. Both esterifying activities were significantly lower than those in nine normal subjects and were correlated with the cholesterol ester concentrations and ester-free ratios *in vivo*. A direct assay for circulating hydrolase was developed, based on the incorporation of 4-^{14}C-cholesterol linoleate into autologous serum substrate. Electrophoretic and radiochromatographic analysis of the substrate sera suggested that most of the ^{14}C-ester was incorporated into lipoproteins, and the validity of the assay was confirmed by its ability to detect known cholesterol ester hydrolase activity in dog serum and hog pancreatic extract. No serum hydrolytic activity was detected in any of the patients, even those with severe hepatic disease. Thus, neither direct nor indirect evidence of circulating cholesterol ester hydrolase was obtained in patients with parenchymal liver disease. Low LCAT activity can entirely account for the impaired *in vitro* cholesterol esterification of hepatic disease and probably contributes to the cholesterol ester derangements seen *in vivo*.

4773 SIGNIFICANCE OF INTRAVASCULAR COAGULATION AND FIBRINOLYSIS IN ACUTE HEPATIC FAILURE. *(E.)* Hillenbrand, P.; Parbhoo, S. P.; Jedrychowski, A.; Sherlock, S. (Roy. Free Hosp., London, England). *Gut* 15(2):83-88, 1974.

Twenty-two patients with acute hepatic failure were studied to determine the incidence and magnitude of intravascular coagulation and fibrinolysis and their relation to the severity of bleeding and prognosis. The mean platelet count, Thrombotest, plasminogen activator, and plasminogen were reduced; the reduction in fibrinogen was not statistically significant. Fibrin/fibrinogen degradation products were only moderately increased. Hepatic fibrin deposition was not extensive, being present in 11 of 22 hepatic sections and appearing more in areas of confluent necrosis than in the sinusoids. The combination of increased fibrin/fibrinogen degradation products and decreased plasminogen activator, plasminogen, and thrombocytopenia is consistent with a diagnosis of intravascular coagulation and secondary local fibrinolysis. However, neither of these processes was severe. The severity of bleeding was related only to the plasminogen levels, and the prognosis was related only to the Thrombotest levels. There was no relation between the hepatic histological and hematological findings. Heparin therapy is not indicated in the routine management of acute hepatic failure, since intravascular coagulation is not severe and heparin may itself cause massive bleeding.

4774 IGM ANTI-I COLD AGGLUTININS IN HEPATITIS MONONUCLEOSA. *(E.)* Ambrus, M.; Bajtai, G.; Peley, I. (County Children's Hosp., Pecs, Hungary). *Folia Haematol. (Leipzig)* 100(4):429-435, 1973.

The immunologic examination of a 10-yr-old girl with hepatitis mononucleosa is presented. The diagnosis was confirmed by biopsy. Anti-I specific cold agglutinins in a titer 1:4096 were found in the patient's serum. The direct Coombs-test was positive at +4°C, but after the washing procedures positive results wer obtained with antihuman globulin serum and B_1C-complement antiserum, but not with monospecific anti-IgG and anti-IgM test sera. After the reduction of the serum with mercaptoethanol, a marked decrease in titer revealed the presence of IgM cold agglutinins, and immune precipitation analysis of the eluate also suggested that IgM type cold agglutinins were present. The eluate reacted with monospecific light chain antisera of the κ-type. The immune globulin concentration of the serum showed an elevation of IgM: 480 mg/100 ml. The test for Australia antigen was negative. The patient has been a normal I phenotype, and the pathologically increased cold agglutinin did not have a hemolytic effect. At the follow-up examination 6 weeks later this agglutinin could not be detected.

4775 EPIDEMIOLOGICAL-CLINICAL CORRELATES OF HEPATITIS B ANTIGEN SUBTYPES. *(E.)* Zuckerman, G. R.; Hacker, E. J.; Aach, R. D. (Washington Univ. Sch. Med., St. Louis, Mo.). *Gastroenterology* 66(4):408-414, 1974.

Hepatitis B antigen (HBAg) in the sera of 135 blood donors and patients with either acute viral hepatitis or chronic liver disease was subtyped. The HBAg in volunteer blood donors was predominantly subtype D (D:Y ratio of 7:1), whereas this subtype was only slightly more common than subtype Y in the sera of patients who had contracted hepatitis following the transfusion of blood from the volunteer donor population. Patients with "needle-stick hepatitis" had almost exclusively subtype Y-HBAg. In contrast, individuals with chronic liver disease had primarily subtype D-HBAg. The patients without recognized exposure ("sporadic hepatitis") had a D:Y ratio of 1.2:1. The age, race, sex, and socioeconomic status of the patients with sporadic hepatitis and subtype D-HBAg were similar to those of individuals with post-transfusion hepatitis. The epidemiological features of the patients with subtype Y-HBAg were similar to those of the patients with needle-stick hepatitis. Many of the former group had histories of close contact with illicit drug users.

4776 EXPOSURE AND IMMUNITY TO HEPATITIS-B VIRUS IN A LIVER UNIT. *(E.)* Reed, W. D.; Mitchell, C. G.; Eddleston, A. L. W. F.; Lee, W. M.; Williams, R.; Zuckerman, A. J. (King's Coll. Hosp., Med. Sch., London, England). *Lancet* 1(7858):581-583, 1974.

Using the leucocyte-migration test, cell-mediated immunity to hepatitis-B antigen (HBAg) was found in 12 (86%) of the 14 members of a liver-unit staff whose work involved frequent contact with purified antigen. In addition, 5 (36%) of them had hepatitis-antibody (HBAb), as indicated by radioimmunoassay. ndings in the other 29 staff members, none of om had knowingly been exposed to infection, did t differ significantly from those in age- and x-matched factory worker controls. Thirty percent the controls showed evidence of cell-mediated munity, and 7% had HBAb. Six patients recovering om acute HBAg-positive hepatitis also had both ll-mediated immunity and HBAb. However, only one the 86 staff members and factory controls tested d ever had clinical hepatitis, and liver function sts were normal. Frequent exposure to low-dose Ag by the oral route may result in a primary immunological response in the gastrointestinal mucosa thout viremia or liver disease; such immunity is kely to be protective.

77 THE LOCATION OF AUSTRALIA ANTIGEN IN THE LIVER AS DEMONSTRATED BY THE DIRECT IMMUNO-LUORESCENCE TECHNIQUE. *(It.)* De Bac, C.; Turbessi, .; Caramia, F.; Ricci, G. (Clin. Infectious Dis., niv. Rome, Italy). *Boll. Soc. Ital. Biol. Sper.* 8(23):1174-1177, 1972.

mmunofluorescence tests for Australia antigen (AuAg), erformed on liver biopsies from 9 AuAg-positive ubjects (7 normal carriers, 1 patient with acute erum hepatitis, and 1 with chronic hepatitis), ere positive in 7 cases. Intranuclear virus-like articles were found in liver tissue from 5 of the subjects examined. All 5 of these subjects had ositive immunofluorescence tests for AuAg. AuAg was ocated primarily in the cytoplasm and, to a more imited extent, in the nuclei of the hepatocytes. lthough these findings provide no information about he relation between AuAg and the virus-like particles, they do confirm that AuAg and virus particles re always found in association in the livers of uAg-positive subjects.

778 DETECTION OF CYTOMEGALOVIRUS ANTIBODIES IN AUSTRALIA-ANTIGEN-POSITIVE AND AUSTRALIA NTIGEN-NEGATIVE HEPATITIS. *(Ger.)* Baals, H.; ulow, B.; Freisenhausen, H. D.; Mai, K. (Inst. ed. Microbiol. Immunol., Univ. Hamburg, Germany). *erh. Dtsch. Ges. Inn. Med.* 78:928-930, 1972.

icro-complement-fixation tests for cytomegalovirus CMV) antibodies, performed on 588 normal blood onors in Hamburg, were positive in 166 (28.2%). hese antibodies were present in 89 of 398 donors ess than 35 yr old (22.4%) and in 77 of the 190 onors 35 yr old or older (40.5%). The difference n the incidence of CMV antibodies between these 2 roups is highly significant. Of 86 adult patients ith hepatitis, biopsies from 50 (58%) were positive or CMV antibodies. Thus the incidence of CMV antibodies is significantly greater in patients with epatitis than in the normal population of Hamburg. f the 86 patients with hepatitis, 38 had positive ests for Australia antigen (AuAg). CMV antibodies ere detected in liver biopsies from 71% of the uAg-positive patients and in only 48% of the AuAg-egative patients. This difference is significant and is even more pronounced in patients less than 35 yr-old. Similar results were obtained in a comparison of the incidence of CMV antibodies in 24 AuAg-positive asymptomatic blood donors. Although these findings show a statistically significant correlation between the incidence of CMV antibodies and AuAg, they provide no evidence of a pathogenetic or immunologic relation between them.

LIVER AND BILIARY TRACT

Chronic Hepatitis

308 VIRAL ANTIBODIES AND AUTOANTIBODIES IN
CHRONIC LIVER DISEASE. *(E.)* Triger, D.
; Kurtz, J. B.; Wright, R. (Royal South Hants
sp., Southampton, England). *Gut* 15(2):94-98, 1974.

ghly significant elevations in the titres to the
ree viruses, measles, rubella, and cytomegalovirus,
re noted in 19 patients (18 females and 1 male,
ed 13 to 81 yr) with chronic active hepatitis.
gnificant elevation in antibody titres to cyto-
galovirus in cirrhotic patients (24 females and 12
les, aged 9-77 yr) was noted. Of these 36 cir-
otic patients, 20 had cirrhosis secondary to al-
hol, 3 had postnecrotic cirrhosis, and 13 had
imary biliary cirrhosis. The titres observed in
e patients and in controls were all within normal
mits to herpes simplex, varicella/zoster, parain-
luenza I, and Mycoplasma pneumoniae. A good corre-
ation was obtained between the immunofluorescent
toantibodies and measles antibody titres, a fair
rrelation with rubella antibody titres, and none
th cytomegalovirus antibody titres. No correla-
on was noted between antimitochondrial antibody
tres and any of the viral antibodies. Absorption
the sera with the measles antigen grown in Vero
lls resulted in the removal of most of the measles
tibody together with the removal of the bulk of
e autoantibodies. Vero cells alone absorbed out
e autoantibodies to a similar extent without sig-
ificantly affecting the measles antibody titre.
us it is suggested that the correlation between
asles antibody titres and autoantibodies is un-
ikely to be due to cross-reacting antigens.

309 MULTIVARIATE ANALYSIS OF SERUM PROTEIN
ASSAYS IN CHRONIC HEPATITIS AND POSTNECROTIC
RRHOSIS. *(E.)* Agostoni, A.; Marasini, B.;
abilini, R.; Del Ninno, E.; Pontello, M. (Inst.
d. Pathol., Univ. Milan, Italy). *Clin. Chem.*
(4):428-429, 1974.

e concentration of 9 proteins in the sera of 98
tients, 29 with chronic persistent hepatitis, 40
th chronic aggressive hepatitis, and 29 with post-
crotic cirrhosis, were studied. The use of a
mited set of serum protein assays for differential
agnosis of these syndromes was tested by multi-
ariate discriminant analysis. Variables which were
atistically significant in contributing to the
scrimination between chronic persistent hepatitis
d chronic aggressive hepatitis were pre-albumin,
gG, IgA, and IgM. A 23% error was found when
ronic persistent hepatitis and chronic aggressive
epatitis were classified by means of the discrimi-
ant based on the 3 Ig only. When pre-albumin was
troduced as a 4th variable, the classification error was only slightly reduced to 21.7%. To discriminate between chronic aggressive hepatitis and postnecrotic cirrhosis, albumin and pre-albumin were most significant, while orosomucoid, β_{1A}-globulin, and IgA ranked next in significance. A 10% error was noted when discrimination was based on all 5 variables. By measuring pre-albumin, albumin, and IgA in serum, chronic aggressive hepatitis and postnecrotic cirrhosis could be differentiated in 89% of the cases. Similar percentages were obtained with albumin, orosomucoid, and IgA; or with albumin, α_{1A}-globulin and IgA.

4810 MICROSOMAL ANTIBODIES IN ACTIVE CHRONIC HEPATITIS AND OTHER DISORDERS. *(E.)* Rizzetto, M.; Swana, G.; Doniach, D. (Mauriziano Hosp., Turin, Italy). *Clin. Exp. Immunol.* 15(3):331-344, 1973.

An autoantibody reacting with microsomal membranes has been characterized by a distinctive immunofluorescence pattern on proximal renal tubules and hepatocytes. The microsomal nature of the antigen was demonstrated by absorption and quantitative complement fixation studies. These results showed the microsomal membrane antibodies are distinct from mitochondrial antibodies found in primary biliary cirrhosis. Microsomal antibodies have been detected in high titers in sera from 16 patients; 12 of these had liver disorders. These consisted of active chronic hepatitis (8 cases); halothane jaundice (2); hepatoma (1); a systemic autoimmune disorder which included chronic hepatitis, hepatomegaly, abnormal liver function tests, a goiter with thyroid antibodies, and a chronic false-positive test for syphilis (1); and an undiagnosed neurological disorder with severe demyelination and subclinical liver disease with periportal lymphoid infiltrates. The titer of these antibodies varied from 1:40 to 1:800 in these 16 patients. Although none of the 8 patients tested repeatedly became negative, antibody titers did decrease in 2 cases. One decrease was associated with a clinical remission of active chronic hepatitis, while another was accompanied by progression to inactive cirrhosis. Microsomal membrane antibodies, although rare, may provide a serological marker for a small proportion of active chronic hepatitis cases differing in several respects from other recognized subgroups in this disease.

4811 CHARACTERIZATION OF THE MICROSOMAL ANTIGEN RELATED TO A SUBCLASS OF ACTIVE CHRONIC HEPATITIS. *(E.)* Rizzetto, M.; Bianchi, F. B.; Doniach, D. (Middlesex Hosp. Med. Sch., London, England). *Immunology* 26(3):589-601, 1974.

Rat liver microsomes were subfractionated into rough and smooth membrane components. Antigen in both subfractions reacted with sera from active chronic hepatitis patients in complement fixation and fluorescence absorption tests. The antigenic determinant appeared to be located on lipoprotein membrance since phospholipases, proteinases and solubilizing procedures reduced the complement fixing activity of the microsome preparations. Further, the antigen was not dependent upon intact ribosomal RNA since treatment with RNase or with EDTA had no effect. IgG isolated from serum of the hepatitis patients and conjugated with peroxidase appeared to react in immunoelectronmicroscopy tests with both the ribosomes and the membrane of the rough endothelial reticulum in rat liver and kidney tissues, but not with ribosomes of smooth endothelial reticulum in these tissues, due, possibly, to destruction of delicate membranes of the latter during preparation of the tissue sections. The ultrastructural appearance of the antigen-antibody interaction was clearly distinguished from that of the mitochondrial primary biliary cirrhosis system.

4812 AUSTRALIA ANTIGEN AND AUTOANTIBODIES IN CHRONIC LIVER DISEASE. *(Ger.)* Muller, R.; Kalden, J.; Deicher, H. (Med. Coll., Hannover, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:926-928, 1972.

Determinations were made of Australia antigen (AuAg), antinuclear and antimitochondrial antibodies, anti-smooth muscle antibodies, and anti-γ-globulin factors in serum from 93 patients with chronic aggressive hepatitis and/or cirrhosis. AuAg was detected in 40 patients (16 with chronic aggressive hepatitis and 24 with cirrhosis) and was absent in 53. Although higher titers were more common in chronic aggressive hepatitis than in cirrhosis, there was no difference between these 2 groups in the frequency of AuAg. Autoantibodies and anti-γ-globulin factors were found in about the same percentage of AuAg-positive and AuAg-negative patients. Follow-ups of AuAg and autoantibodies for more than 2 yr in 8 patients (5 AuAg-positive and 3 AuAg-negative) showed that autoantibodies were not continuously present during this period. No relation was found between the presence or absence of autoantibodies and the course of the disease. Serum transaminase values and IgG levels normalized when AuAg disappeared in a patient who was AuAg-positive for 20 months. The liver then showed almost no sign of inflammation, and no AuAg could be detected in a biopsy by immunofluorescence. These results indicate that there is no justification for classifying patients with chronic liver disease into mutually exclusive antinuclear factor-positive and AuAg-positive groups. The presence of autoantibodies is considered a nonspecific phenomenon associated with chronic liver disease rather than a sign of autoimmune processes occurring in the liver.

4813 OCCURRENCE OF AUSTRALIA ANTIGEN AND ANTINUCLEAR FACTORS IN CHRONIC AGGRESSIVE HEPATITIS. *(Ger.)* Berthold, H.; Maas, D.; Oehlert, W.; Merz, K. P.; Dischler, W. (Hyg. Inst., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:922-926, 1972.

Using the complement-fixation test and immunoelectrophoresis, AuAg was determined in sera from 42 patients with chronic aggressive hepatitis and antinuclear factor and in 23 patients with chronic aggressive hepatitis and no antinuclear factor. Although the complement-fixation test was positive in 28 patients with antinuclear factor, AuAg was detected by both methods in only 3 cases. In contrast, AuAg was present in 16 of the 23 patients who were negative for antinuclear factor. This difference is highly significant. Very high γ-globulin levels were found in most of the patients with antinuclear factor and positive complement-fixation tests who had negative tests for AuAg on immunoelectrophoresis. Since test sera from transfused hemophiliacs contain many antibodies against the various antigenic determinants of IgG in addition to AuAg, there may be a relation between the patients' γ-globulin and isoantigens resulting from multiple transfusion in the test sera. These findings also suggest that 2 or more mechanisms are involved in the development of chronic aggressive hepatitis.

Alcoholic Liver Disease

4818 ELEVATED ANTIHEMOPHILIC FACTOR (AHF, FACTOR VIII) PROCOAGULANT ACTIVITY AND AHF-LIKE ANTIGEN IN ALCOHOLIC CIRRHOSIS OF THE LIVER. *(E.)* Green, A. J.; Ratnoff, O. D. (Case Western Reserve Univ. Sch. Med., Cleveland, Ohio). *J. Lab. Clin. Med.* 83(2):189-197, 1974.

Antihemophilic factor procoagulant activity and levels of antihemophilic factor-like antigen were measured in 22 patients (all males, aged 21-72 yr) with clinical evidence of advanced hepatic cirrhosis. Liver function tests showed that alkaline phosphatase ranged from 18 to 456 IU; SGOT, 50 to 285 IU; total bilirubin, 0.9 to 30.0 mg/100 ml. Elevated levels of procoagulant activity were associated with elevated levels of antihemophilic factor-like antigen as detected by quantitative immunoelectrophoresis. In 13 patients, the elevation of the antigen was significantly higher than that of procoagulant activity. The antigen in cirrhotic plasma was not distinguishable from that in normal human plasma either immunologically or by its filtration characteristics on agarose columns of agarose. An antibody prepared against cirrhotic antihemophilic factor was indistinguishable from that prepared against normal human antihemophilic factor. The results indicate that functional and antigenic antihemophilic factors are the same or closely similar molecules.

4830 THE PORTAL PRESSURE-BLOOD VOLUME RELATIONSHIP IN CIRRHOSIS. *(E.)* Zimmon, D. S.; Kessler, R. E. (VA Hosp., New York, N.Y.). *Gut* 15(2):99-101, 1974.

Portal pressure-blood volume curves were derived in 13 cirrhotic patients with portal hypertension and esophageal or gastric varices by measuring portal pressure at 2 levels of blood volume. Portal pressure varied directly with blood volume. In 7 patients where portal pressure was measured at 3 levels of blood volume separated by 500 ml or more, the portal pressure-blood volume relation was approximately linear. It is hoped that patients with portal hypertension at risk from varieceal hemorrhage may be more precisely managed if the relation between portal pressure and blood volume is emphasized. Knowledge of this relation may help to cope with the hazards of plasma volume depletion leading to hepatic and renal malfunction and plasma volume excess leading to increased portal pressure and its complications.

4831 PLASMA AND URINARY AMINO ACIDS IN INDIAN CHILDHOOD CIRRHOSIS. *(E.)* Vij, S. C.; Maitrya, B. B.; Vij, A. (E. P. Med. Coll., Bikaner, India). *Indian Pediatr.* 9(5):323-324, 1974.

Plasma and urinary amino acids, serum total proteins, serum albumin and globulin fractions were studied in 10 infants with Indian childhood cirrhosis and 10 normal controls. In cirrhotic infants, serum total proteins were not changed significantly but their albumin/globulin ratio was decreased. Increased plasma amino acid levels were associated with aminoaciduria in the cirrhotic infants. These changes could be due to liver function disorders. As a result of this the liver might not be able to synthesize albumin from available plasma amino acids, thereby causing increased plasma amino acid levels and aminoaciduria.

4832 COMPARISON OF RESULTS OF LONG-TERM TREATMENT OF CHRONIC HEPATIC ENCEPHALOPATHY WITH LACTULOSE AND SORBITOL. *(E.)* Rodgers, Jr., J. B.; Kiley, J. E.; Balint, J. A. (Albany Med. Coll., N.Y.). *Am. J. Gastroenterol.* 60(5):459-466, 1973.

Alternate lactulose (50% solution) and sorbitol (60% solution) therapy was employed in a long-term, double-blind study of 3 patients (1 woman and 2 men, aged 60-75 yr) with chronic hepatic encephalopathy. The patients were continued on a 50 g/day protein diet and for the first year were given a 2-month course of one medication (20-30 ml, 3 times/day) followed by a 2-month course on the other. During the 2nd yr, a control period of 2-3 weeks separated treatment periods. Neomycin (2 g/day) was prescribed for mental confusion. A complete blood count and serum electrolytes, blood ammonia, and liver function tests were performed monthly. Periodic electroencephalograms were also done. No patient developed hepatic coma while on either medicine, although 1 required neomycin supplement during 3 of 5 treatment periods with sorbitol. None of the 3 required neomycin during lactulose treatment periods. In 1 patient lactulose seemed more beneficial than sorbitol, as determined by clinical and laboratory criteria. A much larger group of patients must be studied to demonstrate whether lactulose is superior to sorbitol in the treatment of hepatic encephalopathy.

4833 ROENTGENOLOGIC DEMONSTRATION OF SPONTANEOUS REVERSAL OF PORTAL BLOOD FLOW IN CIRRHOSIS AND PRIMARY CARCINOMA OF THE LIVER. *(E.)* Okuda, K.; Moriyama, M.; Yasumoto, M.; Jinnouchi, S.; Shimokawa, Y.; Nakayama, T.; Kanda, Y.; Fukyuama, Y.; Musha, H.; Kuratome, S.; Nakashima, T. (Chiba Univ. Sch. Med., Japan). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):419-428, 1973.

Forty-nine patients with liver cirrhosis and 47 with hepatoma were subjected to at least 2 types of angiographic examination, combined with a barium swallow study designed to detect esophagogastric varices. The angiographic examinations consisted of splenoportography, celiac and superior mesenteric arteriography, hepatic venography, umbilicoportography, celiac and superior mesenteric arteriography, hepatic venography, umbilicoportography, and endoscopy. In 1 cirrhotic patient, an unequivocal retrograde portal blood flow was demonstrated. In 1 hepatoma patient, whose portal vein was visualized during celiac arteriography, the portal flow was to-and-from, the direction depending on the force of the contrast medium injection. In 4 hepatoma patients in whom retrograde portal flow was observed, there were tumor thrombi in the portal vein and, in 1 patient, in the collateral veins. Retrograde portal flow does therefore occur in cirrhosis of the liver, although very rarely; it occurs more often in hepatoma, perhaps due to arterial neovascularization and arteriovenous communications.

4834 USE OF HEMODYNAMIC SELECTION CRITERIA IN THE MANAGEMENT OF CIRRHOTIC PATIENTS WITH PORTAL HYPERTENSION. *(E.)* Smith, G. W. (Baltimore City Hosp., Md.). *Ann. Surg.* 179(5): 782-790, 1974.

Hemodynamic staging was used to study 130 patients (85 males and 45 females, average age 50 yr) with cirrhosis of the liver and portal hypertension. In stage I portal flow is normal; in stage II it is moderately reduced; in stage III it is severely curtailed or even reversed. Both preoperative and intraoperative data were used to judge the hemodynamic stage. Of the 130 patients, nutritional cirrhosis was diagnosed in 90 cases, post-necrotic cirrhosis in 30, and other liver disease in 9. Based largely on hemodynamic selection criteria, 66 patients had a portal-systemic shunt, 24 had a non-shunt operative procedure, and 40 were managed medically. The type of shunt operation was portacaval in 61, mesocaval in 3, and splenorenal in 2. The striking clinical feature was a high operative mortality rate, 35% for shunted patients and 38%

for those treated with a non-shunt operation. Even so, the long-term survival was reasonably good for all three groups of patients, best for those managed by non-surgical means. It was concluded that therapeutic choice based upon hemodynamic criteria decreased the incidence of encephalopathy and eliminated the risk of death from liver failure in selected groups of patients. It was also concluded that, among shunted patients, hemodynamic selection did not improve either operative risk or long-term survival. Finally, it was found that when hemodynamic staging was used to select patients considered hemodynamically unsuitable for a portal-systemic shunt, such considerations led to no improvement in the late results. In an overall consideration of the expense and risk involved in the use of such techniques, and their lack of any definitive clinical benefit, the justification for their continued use is open to question.

4835 FAMILIAL CIRRHOSIS. *(E.)* MacSween, R. N. M.; Fell, G. S. (Dept. Pathol., Univ. Glasgow, Scotland). *Scot. Med. J.* 19(1): 25-30, 1974.

A history is presented for a family in which 7 of 12 sibs died of cirrhosis in adolescence. The histological features of the cirrhosis in these 7 cases were suggestive of Wilson's disease. Two first cousins in this family died in infancy, with a diagnosis of galactosemia, a disease in which cirrhosis may occur. The diagnosis was established by chromatographic demonstration of galactosuria with generalized aminoaciduria. The copper content of the liver was 1099 μg/g dry weight in 1 of the children with histological features of Wilson's disease, compared with 128 μg/g in a "control" cirrhotic liver. The familial occurence of two rare metabolic disorders known to be associated with hepatic cirrhosis has not been previously reported.

4836 SELECTIVE SUPERIOR MESENTERIC ARTERIAL INFUSION OF VASOPRESSIN DURING PORTOSYSTEMIC SHUNT OPERATIONS. *(E.)* Nusbaum, M.; Younis, M. T.; Baum, S.; Blakemore, W. S. (Grad. Hosp., Univ. Pennsylvania, Philadelphia). *Am. J. Surg.*127(1): 35-39, 1974.

Mesenteric arterial infusion of vasopressin (100 U diluted in 500 cc normal saline) as an adjunct during portosystemic shunt surgery was evaluated in a series of 18 patients. Ten had portacaval shunts, 6 had splenorenal shunts, and 2 had mesenteric-caval shunts with an interposed Dacron graft. In 12 patients the catheter was placed in the superior mesenteric artery 1 hr before surgery and then infused with vasopressin for arteriographic assessment of the vascular response. These patients were subsequently taken to the operating room. Bleeding from varices had been controlled in these patients by prior infusion. The other 6 patients were infused with vasopressin from 3 days to 2 weeks without interruption from the onset of bleeding through the shunt operation. As a result of vasopressin infusion, the collateral circulation, at the incision and in the abdomen and retroperitoneum, was markedly diminished. Dissection was performed with greater facility, less blood loss, and shorter operating time. There were 2 deaths in the group. It is concluded that the use of superior mesenteric arterial vasopressin infusion during portosystemic shunts permits more rapid performance of the operation with a relatively avascular field, with fewer anesthetic and intraoperative complications, and without impairment of the hepatic arterial circulation.

4837 SPONTANEOUS REVERSAL OF PORTAL FLOW IN PATIENTS WITH BLEEDING VARICES TREATED BY EMERGENCY PORTACAVAL SHUNT. *(E.)* Charters, III, A. C.; Chandler, J. G.; Condon, J. K.; Grambort, D. E.; Levin, S. E.; Modafferi, T. R.; Orloff, M. J. (Sch. Med., Univ. California, San Diego). *Am. J. Surg.* 127(1):25-29, 1974.

Spontaneous reversal or stagnation of portal blood flow occurred in 32% of 110 patients undergoing emergency portacaval shunt for bleeding esophageal varices, a much higher incidence than has been noted previously. The survival rate was lower in patients with reversed portal flow (37%) than in those with prograde portal flow (56%). The incidence of encephalopathy on admission and that of protein-related encephalopathy after shunt were twice as high in the survivors who had reversed portal flow. These findings indicate that factors other than magnitude of portal flow diversion are important in determining the response to portacaval shunt.

4838 THE VIRAL ORIGIN OF SOME FORMS OF CHRONIC INTRAHEPATIC CHOLESTASIS: A CASE OF CHOLESTATIC JAUNDICE WITH HYPERLIPIDEMIA DEVELOPING INTO A CHRONIC CONDITION. *(Fr.)* Albot, G.; Camilleri, J. P.; Reynes, M. (Hotel Dieu, Paris, France). *Sem. Hop. Paris* 49(52):3481-3495, 1973.

A 61-yr-old woman developed jaundice and symptoms of viral hepatitis 8 days after onset of an influenza-like illness. SGOT values were higher (1000 IU) than those observed in obstructive jaundice. Cholestasis was manifested by pruritis which developed 15 days after onset of jaundice, total bilirubin concentrations of 2 mg/100 ml (primarily conjugated), elevated serum alkaline phosphatase activity (34 Bodansky U), and increased BSP retention. Increases in total lipids (40 g/liter) and cholesterol (20 g/liter) were observed somewhat later. At laparoscopy and laparotomy the liver was green in color and somewhat enlarged. No evidence of cholelithiasis was found and extrahepatic biliary tract was normal. Examination of liver biopsies revealed marked portal and periportal sclerosis, cholestasis with xanthomatosis of Kupffer's cells, almost complete destruction of the portal bile ducts, changes in the bile pole of the hepatocytes, and considerable intralobular histiocytosis. Cholestasis failed to respond to corticosteroids or bile drainage, and prothrombin values progressively decreased. Melena developed and persisted despite therapy, although improvement occurred in clotting factors after administration of ethamsylate and vitamin K_1. The patient went into hepatic coma and died less than 1 yr after onset of symptoms. Although this patient had no antimitochondrial antibodies, which are present in 90-95% of patients with primary biliary cirrhosis, other findings were compatible with biliary cirrhosis. This suggests that viral hepatitis can lead to biliary cirrhosis. Another possibility is that, in unusual cases, cholestatic viral hepatitis may lead to chronic intrahepatic cholestasis with terminal acholangia.

4839 RELATIONS BETWEEN THE INTRAERYTHROCYTE CONCENTRATION OF 2,3-DIPHOSPHOGLYCERATE (DPG) AND THE HALF-SATURATION VALUE (T_{50}-VALUE) IN PATIENTS WITH CIRRHOSIS. *(Ger.)* Baltzer, G.; Auer, H.; Arndt, H.; Englhardt, A.; Martini, G. A. (Med. Clin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1353-1356, 1972.

Since the O_2-dissociation curve is shifted to the right by increasing concentrations of 2,3-diphosphoglycerate (2,3-DPG) in the erythrocytes, measurements were made of the 2,3-DPG and ATP contents of erythrocytes in 27 patients with cirrhosis to determine whether this might account for decreased arterial O_2 saturation. Controls consisted of 17 subjects with normal liver and pulmonary function. Although no appreciable differences were found in the ATP content of erythrocytes in cirrhotics and controls, the mean 2,3-DPG content was significantly higher ($22.8 \pm 6.6 \times 10^{-4}$ μmol/ml) in cirrhotics than in controls ($16.5 \pm 4.9 \times 10^{-4}$ μmol/ml). Since no significant differences were found between the mean half-saturation values for the O_2 dissociation curve in 14 normal subjects and 30 cirrhotics, no relation was found between the erythrocyte 2,3-DPG content and the T_{50} values in cirrhotics. However, the erythrocyte 2,3-DPG content was inversely related to hemoglobin concentrations.

4840 EFFECT OF LARGE DOSES OF ESSENTIAL PHOSPHOLIPIDS, ADMINISTERED I.V. AND ORALLY, ON PROTEIN AND LIPID METABOLISM AND ON ENZYME ACTIVITIES IN PATIENTS WITH CHRONIC LIVER DISEASE. *(Ger.)* Muting, D.; Dohn, P.; Reikowski, J. (Prof. Kalk Clin. Liver Dis., Dig. Metabolic Dis., Bad Kissingen-Hausen, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1389-1392, 1972.

Blood ammonia and free phenol levels decreased significantly and blood urea concentrations increased slightly after i.v. injection of 1000 mg essential phospholipids (EPL) in 24 patients with cirrhosis (12 with and 12 without portal hypertension). EPL apparently increases conjugation of ammonia with glutamic acid to produce nontoxic glutamine and increases free phenol conjugation by increasing glucuronic and sulfuric acid synthesis. Administration of 2700 mg/day of EPL p.o. to 43 patients with chronic liver disease (27 with cirrhosis and 16 with chronic aggressive hepatitis) for an average of 8 months significantly increased the Quick value and significantly decreased blood ammonia levels and BSP retention. In addition, triglyceride levels decreased significantly in patients with cirrhosis. In 31 patients with histologically confirmed fatty liver, EPL (1000 mg i.v. for an average of 6 weeks) significantly reduced blood ammonia, total lipids, total cholesterol, triglyceride, succinate dehydrogenase, and glutamate dehydrogenase levels. A slight transient rebound effect was observed when 4 of these patients were transferred to EPL given p.o. Complete regression of fatty liver occurred in 1 of these patients. When EPL was administered i.v. in large doses, 5 patients developed severe abdominal pain and diarrhea which disappeared after reduction of the dose. No side effects occurred after p.o. administration of EPL.

4841 CHANGES IN SOME STRUCTURAL LIPIDS AND FATTY ACIDS IN THE HUMAN BRAIN IN TOXIC ALCOHOLIC CIRRHOSIS. *(Ger.)* Lesch, P. (Med. Coll., Hannover, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1310-1313, 1972.

Lipids were isolated from the cerebral medulla and cortex of 6 patients who had died of complications of alcoholic cirrhosis. After separation into fractions, fatty acids were determined by gas chromatography and the results compared with those obtained previously on normal brains. In cirrhotic patients decreases were observed in neutral lipids and cerebrosides in both the medulla and cortex. Lecithin, phosphatidylethanolamines, and cholesterol decreased in the medulla, and the sphingomyelin content remained unchanged in both the medulla and cortex. In the cerebroside fraction stearic acid decreased significantly in the medulla but not in the cortex, while nervonic acid (*cis*-15-tetracosenoic acid) decreased in the cortex and increased in the medulla. Relative increases occurred in the contents of myristic, palmitic, and oleic acids in the cortex; palmitic and oleic acid contents decreased in the medulla, and the content of acids with more than 21 C increased. Changes in the fatty acid composition of sphingomyelin paralleled those which occurred in the cerebroside fraction, but the fatty acid composition of lecithin remained unchanged. The palmitic acid content of phosphatidylethanolamines increased from 7.5% to 12.5% in the medulla and from 6.2% to 18.2% in the cortex, while the stearic acid content decreased from 38% to 32% in the cortex and from 23% to 8% in the medulla. The docosatetraenoic acid content increased from 8.0% to 12% in the medulla but remained largely unchanged, along with the arachidonic and docosahexenoic acid contents, in the cortex. Thus, the chain-length of fatty acids generally decreased in the cortex and increased in the medulla along with a slight increase in the content of polyunsaturated acids.

4842 INVESTIGATIONS OF CHANGES IN BILE ACID METABOLISM IN HEPATIC COMA AND PRECOMA. *(Ger.)* Erb, W.; Haase, A.; Walczak, M.; Leuschner, U. (Ctr. Intern. Med., Univ. Frankfurt/Main, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1401-1402, 1972.

Bile acid analyses were performed by gas chromatography on serum from 4 cirrhotic patients in hepatic coma, on liver tissue from 8 patients who had died in hepatic coma, and on serum from normal controls. Serum bile acid concentrations had increased to almost 4000 μg/100 ml in hepatic coma, while a relative decrease was noted in secondary bile acids, particularly deoxycholic acid. Both absolute and relative increases occurred in chenodeoxycholic acid, while cholic acid underwent a relative decrease. The total content of bile acids in liver tissue from patients who had died of hepatic coma was about 1/2 of the normal values. The largest decreases occurred in secondary bile acids and cholic acid, with a far smaller decrease in chenodeoxycholic acid. No decrease occurred in lithocholic acid in either serum or liver, but deoxycholic acid was not detected in the livers of 5 of the 8 patients who had died of hepatic coma. This suggests that bacterial dehydroxylation of chenodeoxycholic to deoxycholic acid no longer occurs since bile acids are not being secreted into the intestine. The ratio of bile acids in 1 g liver to those in 1 ml serum was increased in hepatic coma due to a decrease in reabsorption of bile acids from the portal vein by the liver and passage of bile acids from the liver into the serum as a result of damage to the membranes of liver cells. Bile secretion is also greatly reduced or abolished and the bile acid pool is reduced in hepatic coma so that the total bile acid content of the liver decreases.

4843 NUMERICAL TAXONOMIC ANALYSIS OF CIRRHOSIS. II. CLINICAL SIGNIFICANCE OF CLASSIFICATIONS. *(E.)* Winkel, P.; Tygstrup, N. (Rigshosp., Copenhagen, Denmark). *Comput. Biomed. Res.* 7(2):17-126, 1974.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

4861 CEPHALOTHIN LEVELS IN HUMAN BILE. *(E.)* Ram, M. D.; Watanatittan, S. (Huron Rd. Hosp., Cleveland, Ohio). *Arch. Surg.* 108(2): 187-189, 1974.

Cephalothin sodium levels in serum, gallbladder bile, gallbladder tissue, and common duct bile were studied in 27 patients, 4 of whom were operated on for abdominal conditions other than biliary tract disease, 12 of whom were undergoing cholecystectomy for cholelithiasis or chronic cholecystitis or both, 4 patients with obstructive jaundice, and 7 patients who had a T-tube in their common bile duct following surgery. The first 20 patients above received cephalothin (8 gm, i.v., in 2 gm/6 hr doses). Results indicated that cephalothin is concentrated in bile in normal patients and patients with gallbladder disease. In the presence of jaundice, results are less conclusive. Peak levels in bile were reached 2 hr following a single dose of the drug. The level at 8 hr was less than 1 μg/ml in patients with biliary drainage through a T-tube in the common bile duct. Thus the drug must be given every 4 or 6 hr to maintain adequate concentration in the bile. Since the antibacterial spectrum of cephalothin includes a large number of common biliary pathogens, and since the concentration of the drug in bile reaches levels higher than the minimal inhibitory and even bactericidal concentration in the absence of obstructive jaundice, it may be of use in treating biliary infections.

4862 THE SEQUENTIAL DEPOSITION OF CRYSTALLINE MATERIAL IN GALLSTONES: EVIDENCE FOR CHANGING GALLBLADDER BILE COMPOSITION DURING THE GROWTH OF SOME STONES. *(E.)* Sutor, D. J.; Wooley, S. E. (Dept. Chem., Univ. Coll., London, England). *Gut* 15(2):130-131, 1974.

Determination of the sequential deposition of crystalline compounds in a representative collection of gallstones from 578 patients has been made. Of the 578 stones, 249 were composed entirely of cholesterol or of cholesterol plus the small white beads of calcium palmitate, 77 were entirely calcium salts, 242 contained both cholesterol and calcium salts in varying proportions, and 10 were of amorphous or unidentified material. In 76 of the 207 stones possessing both compounds from which several samples could be taken, the compounds were present in an intimate mixture throughout the stones. In the remaining 131, however, a change in composition occurred during growth. Generally a central nucleus composed of one of these types of compound is surrounded by outer layers formed of a mixture of both, or vice versa. In a few stones there was a change from one type of compound to the other occurring in successive layers. Changes in the number and type of calcium salts precipitated, as well as changes in the crystalline form of calcium carbonate and calcium phosphate, occurred. It is suggested that such changes in gallstone composition may indicate changes in gallbladder bile composition or alterations in the composition of hepatic bile. Loss of gallbladder function could result in the cessation of calcium salt deposition.

4863 THE TREATMENT OF RETAINED STONES IN THE COMMON BILE DUCT WITH SODIUM CHOLATE INFUSION. *(E.)* Lansford, C.; Mehta, S.; Kern, Jr., F. (Univ. Colorado Med. Ctr., Denver). *Gut* 15(1): 48-51, 1974.

Stones were retained in the common bile duct after cholecystectomy and common duct exploration in 6 patients, (4 females and 2 males, aged 19-60 yr). They were treated by sodium cholate infusions through the T-tube. In 4 of the 5 patients in whom the stone or stones were located between the T-tube and the duodenum, treatment was successful within 5 days. In the 5th case, the stone passed after 2 weeks. In 3 of these patients a stone became transiently impacted in the distal bile duct causing a rise in intraductal pressure and pain in the epigastrium and back. Mild, transient pancreatitis developed in 2 cases. Diarrhea occurred in all but was easily controlled with cholestyramine. The one failure was a case in which the stone was located proximal to the tube. In this patient, who was given sodium cholate and sodium deoxycholate, the diarrhea became uncontrollable and treatment was discontinued. Thus it is suggested that infusion of sodium cholate into the common bile duct be used in the treatment of stones retained between the T-tube and the duodenum.

4864 STRATIFICATION OF BILE. *(E.)* Wright, J. T. (Sydney Hosp., Australia). *Aust. Radiol.* 17(2):157-164, 1973.

Stratification in the cholecystogram occurs in most normal people after an all-night fast and before the first meal of the day. It disappears shortly afterwards. It is a normal finding and its transient nature makes it unlikely that it would be a gallstone precursor. Differences observed in the layering phenomenon appear to be due to differences in the times when exposures are made, rather than to differences in contrast media. Although most of the author's observations support the view that stratification is due to inspissated bile, there remain a few cases in which layering occurs with stasis, where excessive inspissation and stone formation would be a possibility. One patient with a history suggestive of cholelithiasis showed marked layering and edge-ring phenomenon in both erect and supine positions on i.v. cholecystography. Since it was feared that gallstones might be concealed in the layer, a 3-day telepaque test was performed and revealed 3 translucent calculi. At cholecystectomy, performed 8 days later, the stones were removed and a high concentration of contrast medium was still present in the gallbladder.

4865 ACUTE NONLITHIASIC CHOLECYSTITIS IN MULTIPLE TRAUMA: A HYPOTHESIS ABOUT ITS ETIOLOGY. THE ROLE OF LYSOLECITHINS. *(Fr.)* Inglesakis, J. A.; Lanfranchi, J. P.; Migliori, G.; Michelangeli, F.; Le Bras, A.; Etienne, A. (St. Roch Hosp., Nice, France). *Nouv. Presse Med.* 3(1):19-21, 1974.

Case reports are presented for 3 patients who developed acute cholecystitis 10-28 days after suffering severe generalized trauma. All 3 patients developed fever, jaundice, and dyskinesia manifested by diffuse abdominal distension and intestinal paresis. Elevated serum alkaline phosphatase activities were found in 2 of the patients. The late onset of cholecystitis is attributed to administration of large doses of antibiotics. At surgery one patient was found to have a subhepatic abscess surrounding a perforated gallbladder. Since 2 of these patients developed fat embolisms, it is suggested that serum lipase, which is activated in this condition, acts on biliary lecithins. The lysolecithins thus liberated might induce lesions in the gallbladder or even the entire biliary tract. Bacteremia and biliary stasis may also play a role.

4866 INFLAMMATORY STENOSIS AT THE JUNCTION OF THE RIGHT AND LEFT HEPATIC DUCTS. *(Fr.)* Roux, M.; Delavierre, P.; Vayre, P.; Hureau, J.; Paolaggi, J.; Levasseur, J.-C. (Vaugirard Hosp., Paris, France). *Sem. Hop. Paris* 49(28):2081-2082, 1973.

A 35-yr-old woman was hospitalized with jaundice which had developed 4 months previously 6 weeks after an episode of severe pain in the right lumbar region which radiated upwards. The patient had been jaundiced at birth and had an unspecified liver disorder as a child. Jaundice was associated with pruritis; hepatomegaly; increased SGOT, SGPT, and serum protein levels; and positive turbidity tests. At surgery the findings included chronic atrophic cholecystitis with no evidence of gallstones and a hard nodule causing stenosis at the junction of the left and right hepatic ducts. Since the nodule was believed to be neoplastic, a hepaticojejunostomy was performed and the patient was given cyclophosphamide before discharge. One yr after surgery the patient became asthenic and developed dyspeptic symptoms, but a radiological examination showed that the anastomosis was functioning perfectly. An enlarged inguinal lymph node which appeared 5 yr after surgery was found to be benign on histological examination. Since more than 5 yr have passed since surgery with no recurrence, it is considered that the patient probably had inflammatory stenosis rather than a carcinoma.

4867 INCREASED BACTERIAL DEGRADATION OF BILE ACIDS IN CHOLECYSTECTOMIZED PATIENTS. *(E.)* Hepner, G. W.; Hofmann, A. F.; Malagelada, J. R.; Szczepanik, P. A.; Klein, P. D. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 66(4):556-564, 1974.

Bile acid metabolism was studied in 12 healthy subjects, 13 patients with cholesterol gallstones, and 10 patients who had undergone cholecystectomy for cholesterol gallstones. Compared with the healthy subjects, the cholecystectomized patients showed significantly increased bacterial deconjugation and 7-dehydroxylation of [2,4-^{3}H]cholyl-[1-^{14}C]glycine. However, the pool of cholylglycine was considerably smaller, so that the absolute rate of deconjugation was similar. The pool of deoxycholylglycine was twice as large as that in the healthy and diseased controls. In addition, ketohydroxy bile acids (resulting from bacterial dehydrogenation) composed 7 to 15% of the bile acid pool. The 7-keto and 12-keto derivatives of cholic acid were identified by mass spectrometry. The total bile acid pool in the cholecystectomized patients did not differ from that in the healthy controls, but it was larger than that in the diseased controls. The size of the total bile acid pool in the cholecystectomized patients correlated closely with the size of the secondary bile acid pool. The apparent return of the total bile acid pool to a normal size after cholecystectomy can be explained in part by the increased input of secondary bile acids from the intestine.

4868 EFFECT OF BILE ACID FEEDING ON CHOLESTEROL METABOLISM IN GALLSTONE PATIENTS. *(E.)* Hoffman, N. E.; Hofmann, A. F.; Thistle, J. L. (Mayo

Grad. Sch. Med., Rochester, Minn.). *Mayo Clin. Proc.* 49(4):236-239, 1974.

An isotope dilution technique was used to determine the exchangeable cholesterol pool and the cholesterol input to the pool in 23 patients with gallstones. Eight were receiving chenodeoxycholic acid (10.0-25.0 mg/kg), 7 cholic acid (7.0-33.0 mg/kg), and 8 a placebo. The patients had been under treatment for at least 6 months prior to the trial, and they remained on their regimen during the 6 months required for measurement of the serum specific activity decay curve. The exchangeable cholesterol pool and cholesterol input were similar in all three groups and the values obtained were nearly identical to those reported by others for patients without gallstones. In a larger group of patients receiving these treatments, the serum cholesterol levels did not change in any of the groups. Triglyceride levels decreased in patients receiving chenodeoxycholic acid, but the magnitude of the change was only about 20%; triglyceride levels remained unchanged in the cholic acid and placebo groups. Thus, p.o. administration of chenodeoxycholic acid does not appear to cause any major change in the body's cholesterol or lipid metabolism while it does decrease cholesterol saturation in the bile and induces gallstone dissolution.

GENERAL

4892 TREATMENT OF DIARRHEA IN MALNOURISHED INFANTS AND CHILDREN. A DOUBLE-BLIND STUDY COMPARING AMPICILLIN AND PLACEBO. *(E.)* Garcia de Olarte, D.; Trujillo, H.; Agudelo, N.; Nelson, J. D.; Haltalin, K. C. (Fac. Med., Univ. Antioquia, Medellin, Columbia). *Am. J. Dis. Child.* 127(3): 379-388, 1974.

Rectal swabs and stool specimens for culture were collected from 2,236 infants and children hospitalized for severe diarrhea in Medellin, Colombia, during a 2-yr period. Salmonellae were identified in 280, enteropathogenic *Escherichia coli* in 117, and shigellae in 61 specimens. It was noted that, had only stool specimens been collected, almost half of the pathogens would have been overlooked. Ampicillin or placebo treatment given parenterally or orally for 5 days was offered randomly to 186 patients with enteropathogens and 96 with acute diarrhea of unknown cause. No adverse or beneficial effect of ampicillin was found in infants with enteropathogenic *E. coli*, even though the infecting strains were susceptible *in vitro* to ampicillin. Similarly, no effects were noted in patients with diarrhea of unknown cause. For *Salmonella* infection, orally given ampicillin was equivalent to placebo therapy. However, there was 100% bacteriologic cure without short-term relapse in those given ampicillin intramuscularly. This was a statistically significant difference from placebo or orally given ampicillin treatment. Ampicillin therapy for shigellosis substantially shortened the period of diarrhea, fever and positive stool cultures compared with placebo treatment. The overall mortality among the 282 patients who did not possess other infectious processes in addition to diarrheal disease was 4.3% (12 deaths). Six of the 12 deaths occurred in infants with diarrhea of unknown cause, resulting in a mortality of 6.3% for this group of 96 patients. Mortality among the patients with pathogens was: *shigellae*, 8.1% (3 of 37); *salmonella*, 1.8% (2 of 110); EPEC, 2.9% (1 of 35).

4893 STUDIES ON THE ENTAMOEBA HISTOLYTICA BILE SALT INTERACTION. *(E.)* Gupta, K. G.; Arora, P. K.; Bhalla, V. K. (Dept. Microbiol., Panjab Univ., Chandigarh, India). *Zentralbl. Bakt. Hyg. Orig. A* 225(4):546-552, 1973.

The interaction of *Entamoeba histolytica* with bile salts/acids was studied. The results indicate that some isolates of *E. histolytica* had the capacity to transform cholic to deoxycholic acid in addition to an unidentified metabolite of rf 0.43. Some of the isolate of *E. histolytica* could deconjugate glycholic, glycodeoxycholic and taurodeoxycholic acids with the formation of cholic and deoxycholic acid resp., in addition to some other metabolites. Statistical analysis showed the effect of bile salts on trophozoite formation was not significant. Only deoxycholate on isolate No. 3172 was shown able to impair the cyst formation ability, while other bile salts/acids were insignificant in this respect.

Thus it was concluded that bile salts/acids do not exhibit antiprotozoal effects of significant measure. Although only a small number of patients was examined, it was noted that lithocholic acid was absent in all dysentery patients and present in all normal subjects.

4894 JUVENILE GASTROINTESTINAL POLYPOSIS IN A FEMALE INFANT: REPORT OF A CASE AND REVIEW OF THE LITERATURE OF A RECENTLY RECOGNIZED SYNDROME. *(E.)* Sachatello, C. R.; Hahn, I. S.; Carrington, C. B. (Univ. Kentucky Med. Sch., Lexington). *Surgery* 75(1):107-114, 1974.

A white female infant (age 2 months) was hospitalized for pneumonia. Examination yielded the diagnosis of interventricular septal defect. Multiple polyps were located in both large and small intestine at 5 months of age and a Meckel's diverticulum was removed. At 10 months of age rectal prolapse of multiple polyp-studded mucosa developed and 6 polyps were removed during sigmoidoscopy at this time. Peripheral edema was noted at 1 yr of age. At 14 months a second laparotomy was performed to remove a large gastric polyp and innumerable polyps in the small intestine. A subtotal colectomy was also performed. At 22 months physical examination showed a cachectic child with prominent abdominal distention and rectal prolapse. Cardiomegaly, a loud systolic murmur, clubbing of the fingers, and hepatomegaly were also noted. Multiple polyps were removed from the stomach and the small and large bowel. The patient died in the immediate postoperative period. Based on a review of 7 cases, the composite picture of an infant with juvenile polyposis would be development of diarrhea, either bloody or mucoid, associated with anemia, failure to thrive, and increased susceptibility to pneumonia. Rectal prolapse develops between 8 to 10 months of age. For supportive treatment it is suggested that the diarrhea be treated vigorously with fluid replacement and specific antidiarrheal medication. A broad spectrum of antibiotic agents should be tried along with oral elemental diet preparations to perhaps lessen the roughage content. Prolonged i.v. hyperalimentation may be advantageous. For operative treatment of rectal prolapse, as many rectal polyps as possible should be removed, fulguration is appropriate. For intestinal polyps, recurrent severe blood loss requiring transfusions, persistent diarrhea with weight loss, or signs of partial small bowel obstruction suggest resection of the terminal ileum and colon (usually the most severely involved parts of the gastrointestinal tract). Juvenile polyposis of infancy is characterized by gastrointestinal bleeding, diarrhea, recurrent rectal prolapse, inanition, and intussusception. Prognosis depends on the severity and extent of involvement. Of the 7 infants with extensive juvenile polyposis studied here, 6 died before the age of 2 yr.

4895 LAXATIVE-INDUCED DIARRHOEA: A CONTINUING CLINICAL PROBLEM. *(E.)* Cummings, J. H.; Sladen, G. E.; James, O. F. W.; Sarner, M.; Misiewicz, J. J. (Central Middlesex Hosp., London, England). *Br. Med. J.* 1(5907):537-541, 1974.

Case histories are presented for 7 women, age 26-65 yr, who spent an average of 127 days in the hospital for extensive investigation of abdominal pain, diarrhea, and weight loss due to excessive taking of laxatives. All 7 denied taking laxatives and none displayed the characteristic features of the effects of cathartics on the colon on sigmoidoscopy or radiological examination. Hypokalemia and other electrolyte abnormalities were common and were initially thought to be due to a combination of severe diarrhea and vomiting. Biopsies of the rectal mucosa were abnormal only in 3 patients who had taken senna preparations. In 6 of these 7 patients, one or more of the following abnormalities were found: steatorrhea, low urinary xylose excretion, vitamin B_{12} malabsorption, duodenal ileus, abnormal pancreatic scan, abnormal gastrointestinal hormone assays, and achlorhydria. The diagnosis was not easy and was finally established either by analysis of the urine and stools or by searching the patient's ward locker.

4896 ISOENZYME STUDY ON POSTOPERATIVE TRANSIENT HYPERAMYLASEMIA. *(E.)* Harada, K.; Kitamura, M.; Ikenaga, T. (Toranomon Hosp., Tokyo, Japan). *Am. J. Gastroenterol.* 61(3):212-216, 1974.

Total serum amylase activity levels and isoamylase patterns were studied pre- and postoperatively in 113 patients who underwent various surgical procedures. Similar determinations were simultaneously made of urinary amylase in 19 of these patients. Total serum amylase activity was elevated in the 1st and 2nd postoperative days in 18 patients or 16% of the cases. In all cases serum amylase activity returned to normal between the 2nd and 4th postoperative day without special treatment. None of the patients with hyperamylasemia had clinical symptoms of acute pancreatitis. Good correlations were found between serum and urinary amylase levels. In 12 patients with postoperative hyperamylasemia most of the amylase activity was found in the pre-γ-globulin zone on agar gel electrophoresis. This amylase was therefore considered to be of extrapancreatic origin. In 5 patients with only slightly increased activities and in a 6th patient who underwent pancreaticoduodenectomy for cancer of the ampulla of Vater, most amylase activity was located in the fast-γ-globulin zone. The isoamylase in these cases was interpreted as pancreatic in origin. The mechanisms responsible for transient postoperative hyperamylasemia and the origin of amylase causing the rise are not yet clear. Hence, hyperamylasemia following surgical procedures should not be interpreted as the result, in all instances, of postoperative pancreatitis.

4897 IDIOPATHIC GASTROINTESTINAL BLEEDING AND AORTIC STENOSIS. *(E.)* Cody, M. C.; O'Donovan, P. B.; Hughes, R. W. (Mayo Clin., Rochester, Minn.). *Am. J. Dig. Dis.* 19(5):393-398, 1974.

In a review of the Mayo Clinic patient population from 1964 through 1969, 610 patients with valvular heart disease were sampled. Of these 610, 275 had aortic stenosis, 7 of whom also had idiopathic gastrointestinal bleeding. Patients were excluded

rom the idiopathic category if they had
iaphragmatic hernia, diverticulosis, or a
istory of ulcerogenic drug intake. The control
roup, composed of the remaining 335 patients,
ad no idiopathic gastrointestinal bleeding.
ne prevalence rate for idiopathic gastrointestinal
leeding in patients with aortic stenosis was
.6%, a rate significantly different from that
f the controls. The prevalence rate for idiopathic
astrointestinal bleeding by coded diagnosis for
ne 1967 Mayo Clinic population was 0.025%. This also
nowed a significant increased risk of idiopathic
astrointestinal bleeding in aortic stenosis.
ne number of cases with this association were too
ew to draw valid conclusions concerning the
atural history of these two related conditions.
owever, the most likely explanation appears to be
n intermittent or sustained decrease in mesentery
rtery perfusion, resulting in anoxic damage
nd bleeding in the bowel.

398 THE EFFECT OF R-FACTOR CARRIAGE ON THE SURVIVAL OF Escherichia coli IN THE HUMAN INTESTINE.

(E.) Anderson, J. D.
led. Sch., Univ. Bristol, England). *J. Med.*
icrobiol. 7(1):85-90, 1974.

ne survival of "marked" strains of *Escherichia*
oli with antibiotic-resistance-transfer (R)
actors was studied in the feces of 12 healthy
man volunteers (9 males and 3 females) for 7 days
fter ingestion. Resistance to ampicillin/chlor-
phenicol/kanamycin/streptomycin/sulphonamides
nd to chloramphenicol/streptomycin/sulphonamides/
etracyclines were determined in 14 experiments
n the 12 subjects. Strains without R factors
erved as controls. Chromosomally determined re-
istance markers were used to identify both R-
actor-bearing and R-factor-free strains. In 52
f 54 fecal samples studied, the R-factor-bearing
rganisms were isolated in fewer numbers than the
ontrols. In the 2 samples in which the reverse
ccurred, the effect was not marked. Generally the
all in the number of R-factor-bearing organisms
as progressive, and 4 days after ingestion the
ean fecal population of R-factor-bearing organisms
as only 0.5% of the control organisms. The re-
ative decline in the R-factor population probably
esulted from impaired vitality of organisms bearing
nese plasmids rather than from loss of R factors
rom the cell.

399 GASTROINTESTINAL BLEEDING IN MILD VON WILLEBRAND'S DISEASE.

(E.) Nilsson, L.
; Blomback, M. (Karolinska Inst., Stockholm,
weden). *Rendic. Gastroenterol.* 5(2):90-96, 1973.

n 14 patients from a series of 52 patients with re-
eated melena, no lesion of the gastrointestinal
ract could be demonstrated in spite of very careful
nvestigations. Eight of these patients were sent
or coagulation analyses and in 5 a coagulation de-
iciency was demonstrated. Four were shown to have
mild form of von Willebrand's disease and one an
nknown coagulation disorder. Three other patients,
rom the same clinic, with repeated melena were also
investigated and found to have von Willebrand's disease, mild form. It is stressed that the bleeding history as well as the family history might indicate in which patients with melena of obscure origin a detailed coagulation investigation should be made.

4900 DIFFUSE EOSINOPHILIC GASTROENTERITIS.

(E.) Goldberg, H. I.; O'Kieffe, D.; Jenis, E. H.; Boyce, H. W. (Univ. California Sch. Med., San Francisco). *Am. J. Roentgenol. Radium Ther. Nucl. Med.* 119(2):342-351, 1973.

The roentgenographic findings for 4 men (aged 21-28 yr) with diffuse eosinophilic gastroenteritis and 48-69% peripheral blood eosinophils are presented. All patients exhibited extensive duodenal, jejunal, and proximal ileal involvement and in 3 there was concomitant gastric involvement affecting the antrum. Eosinophilic infiltration of the small bowel mucosa and lamina propria, confirmed by autopsy, resulted in regular nodular contour defects consisting of thickened circular folds. More extensive involvement of the bowel or transmural involvement resulted in distorted folds with irregular angulation and a saw-toothed contour of the small bowel; in 1 case the folds were completely effaced, causing narrowing of the bowel lumen. Separation of bowel loops was observed in 3 patients. The roentgenographic evidence of eosinophilic infiltration was completely reversed by systemic steroid therapy (15-40 mg/day prednisone). However, peripheral eosinophil counts remained elevated (10-20%) in 2 patients.

4901 TRANSMISSIBLE GASTROENTERITIS: MECHANISMS RESPONSIBLE FOR DIARRHEA IN AN ACUTE VIRAL ENTERITIS IN PIGLETS.

(E.) Butler, D. G.; Gall, D. G.; Kelly, M. H.; Hamilton, J. R. (Dept. Pediat., Univ. Toronto, Canada). *J. Clin. Invest.* 53(5): 1335-1342, 1974.

Young piglets (3 weeks old) were studied 40 hr after experimental infection with transmissible gastroenteritis virus to identify the mechanisms of diarrhea in this disease and to better understand infectious diarrhea in humans. Using continuous segmental marker perfusions in 4 regions along the gut, significant increases in net intraluminal accumulation of water and electrolytes appeared only in the proximal jejunum, the region infected by the virus. In this jejunal segment studied *in vivo*, unidirectional sodium flux, extracellular fluid to lumen, significantly increased, lumen to extracellular fluid significantly decreased, compared with match-fed littermates. Transmissible gastroenteritis did not alter gross villous structure or intraluminal bacteria, bile salts, lactate, pH, or osmolality. Epithelial cell migration was accelerated in the jejunum of infected pigs. Isolated in suspension, these cells from transmissible gastroenteritis pigs exhibited increased active and passive sodium efflux, cells from mannitol-perfused pigs exhibited only increased active sodium efflux. In this viral enteritis, altered sodium transport in the jejunum, the region of the intestine infected appears to be associated with defective epithelial cell function.

4902 INTESTINAL CANCER IN THE PEUTZ-JEGHERS SYNDROME: A RE-EVALUATION. *(E.)* Reid, J. D.; Petrelli, M. (Cleveland Metropolitan Gen. Hosp., Ohio). *Ohio State Med. J.* 70(4):231-235, 1974.

Among 492 cases of the Peutz-Jeghers syndrome reported through December 1972, 16 (3.2%) have had metastasizing carcinoma and a further 17 (3.4%) have had locally invasive or *in-situ* cancer. Although no increased frequency can be established by statistical analysis, the relatively early age at which cancers have developed, the unusual proportion in the small intestine, and the unusual involvement of both antrum and duodenum in continuity, suggest that there is a small but real addition to the ordinary risk of malignancy. The polyps in the Peutz-Jeghers syndrome are predominantly hamartomas but may contain epithelium with the characteristics seen in ordinary adenomas. Malignant change in polyps has been established but is rare. The practical significance of these findings is that complete disregard for malignant change is unjustified, while overzealous surgical intervention remains unwarranted.

Parasitology

4946 THE CHANGING PATTERN OF HYDATID DISEASE, WITH SPECIAL REFERENCE TO HYDATID OF THE LIVER. *(E.)* Joske, R. A. (Dept. Med., Univ. Western Australia, Perth). *Med. J. Aust.* 1(5):129-132, 1974.

A survey is presented of 86 patients with hydatid disease who were admitted to 3 teaching hospitals in Australia in the 15 years from 1957-1971. The frequency of admissions did not change significantly during this period. There were 47 males and 39 females. Of the 86 patients, 58 were over 40 yr old and only 10 were below 20. The majority of patients (57) were Australian born; 15 of the 57 were Aboriginals. The most frequent site of infestation was the liver, which was involved in 61 cases and was the sole site in 49 of these. Other intraabdominal hydatids were present in 7 patients, and 3 others had peritoneal hydatids without hepatic disease. The lung was affected in 23 cases, being the only site of disease in 16 cases. Liver and lung were both involved in 6 cases. Other sites such as kidney, brain, and musculoskeletal organs accounted for 7 cases. Hepatic involvement was significantly more common in patients aged over 40 yr, compared with younger patients. There was a significant excess of extra-hepatic hydatids in Australian-born patients compared with immigrants. There were 61 patients with hydatid of the liver, but in 31 this was an incidental finding unrelated to the cause of admission to hospital. The most frequent presentation of the symptomatic patients was liver enlargement (13 cases). Hematological studies showed few significant abnormalities. Radiological examination was of more diagnostic value. The most significant combination of biochemical results was slight elevations in the levels of serum bilirubin and alkaline phosphatase. The continued occurrence and protean manifestation of hydatid disease mean this condition must still be considered in the differential diagnosis of obscure cases, especially with hepatic or pulmonary manifestations, and in elderly patients.

GENERAL

Regional Enteritis

4949 MIXED-LYMPHOCYTE REACTION AS A MEASURE OF IMMUNOLOGICAL COMPETENCE OF LYMPHOCYTES FROM PATIENTS WITH CROHN'S DISEASE. *(E.)* Richens, E. R.; Williams, M. J.; Gough, K. R.; Ancill, R. J. (Dept. Pharmacol., Univ. Bath, England). *Gut* 15(1): 24-28, 1974.

Peripheral blood lymphocytes from 12 patients with Crohn's disease and from a group of normal volunteers have been tested for transformation under stimulation of allogeneic cells in a mixed lymphocyte culture and by phytohaemagglutinin *in vitro*. There was a significant depression of transformation in the mixed lymphocyte culture where lymphocytes from the Crohn's disease patients constituted the responding population. With phytohaemagglutinin stimulation, no difference in transformation was seen between the patients and the control group. This appears to indicate a depression in cellular immunity in Crohn's disease.

4950 GRANULOMATOUS ENTEROCOLITIS IN CHILDHOOD AND ADOLESCENCE. *(E.)* Guttman, F. M. (Jewish Gen. Hosp., Montreal, Canada). *J. Pediatr. Surg.* 9(1):115-121, 1974.

Granulomatous enterocolitis was studied in 52 patients (27 males and 25 females) who had contracted the disease between the ages of 2 1/2 and 19 years. They were followed for 1-24 yr. Early manifestations of the disease, particularly fever of unknown origin and failure to grow, were frequently evident many years before the onset of bowel disease. Abdominal pain was the most frequent symptom. Granulomatous ileocolitis was present in 12 patients, ileitis and jejunitis in 8, and terminal ileitis in 32. Half of those on medical management are doing well. Of 19 patients operated on, 12 did very well and 4 suffered recurrences. Appendectomy after an acute illness was followed by remission in only 3 of 15 patients. Of these 15, 7 required another operation and 4 others had several hospitalizations for recurrent disease. This does not suggest that acute ileitis is a separate entity from chronic granulomatous disease. Of the 6 patients with severe growth retardation, 3 had growth spurts after operation. It is suggested that, although surgery itself does not stimulate growth, it controls the disease for 1-2 yr and thereby allows growth to occur. In a low but meaningful percentage of cases, the surgery provides a long-term respite from symptoms. The operation, which represents an immediate risk to life of 3%, should probably be made more frequently than it currently is in younger patients since much more longlasting results occur in this age group.

4951 EFFECT OF ADMINISTERED HUMAN GROWTH HORMONE ON GROWTH RETARDATION IN INFLAMMATORY BOWEL DISEASE. *(E.)* McCaffery, Jr., T. D.; Nasr, K.; Lawrence, A. M.; Kirsner, J. B. (Louisiana State Univ. Sch. Med., New Orleans). *Am. J. Dig. Dis.* 19(5):411-416, 1974.

In a previous study of 22 severely growth-retarded children with inflammatory bowel disease, endocrinologic evaluation revealed hypogonadism and low growth hormone levels. This was attributed to a secondary hypopituitarism. In order to assess this hypothesis, (2 males, aged 16 and 20 yr), from this group and another 16-yr-old male who was not so severely growth-retarded as to be included in the initial study were given human growth hormone replacement (3 mg 3 times a week) for all 3 patients had no evidence of inflammatory bowel disease for at least 6 months before and during the course of this investigation. No significant height increment could be attributed to the human growth hormone administration, although a definite anabolic response was present in each patient during the trial. It appears that the youngsters with inflammatory bowel disease may have a relative end-organ resistance to the metabolic and growth-promoting effects of human growth hormone and that their growth problems are not related to hypopituitarism.

4952 PNEUMATOSIS COLI IN CROHN'S DISEASE. *(E.)* Ghahremani, G. G.; Port, R. B.; Beachley, M. C. (Univ. Chicago Pritzker Sch. Med., Ill.). *Am. J. Dig. Dis.* 19(4):315-323, 1974.

Two cases of extensive pneumatosis of the colon associated with Crohn's disease are reported. This unusual complication most likely resulted from the intramural dissection of bowel gas due to altered mucosal integrity and increased intraluminal pressure. In these two cases, the submucosal and subserosal collections of gas did not involve the small intestine. The diagnosis of Crohn's disease was established by clinical, radiological, and pathological examinations prior to the development of pneumatosis coli. In the first case, laparotomy was performed when both diseases were in the active phase and displayed their typical features in the resected specimen. In many cases it might be difficult for the pathologist to correctly diagnose and differentiate the two disease processes since their histopathological features (i.e., dilated lymphatic channels and a chronic inflammatory reaction including plasma cells, lymphocytes, eosinophilic leukocytes, giant cells, and granulomas) are similar.

4953 LEUCOCYTE MIGRATION STUDIES IN CROHN'S DISEASE USING CROHN'S COLON HOMOGENATE AND MITOCHONDRIAL AND MICROSOMAL FRACTIONS. *(E.)* Richens, E. R.; Williams, M. J.; Gough, K. R.; Ancill, R. J. (Roy. United Hosp., Bath, England). *Gut* 15(1):19-23, 1974.

Leukocytes from 38 patients (14 males and 23 females, mean age 41 yr) with Crohn's disease were tested for evidence of migration inhibition in the presence of preparations of colon from a patient with this disease. Controls consisted of 12 normal subjects. Abnormal leukocyte migration values were obtained for 18 of 32 patients with crude colonic mucosal homogenate, for 17 of 29 patients with the colonic mitochondrial fraction, and for 22 of 36 patients with the colonic microsomal fraction. No abnormal values were observed in any of the controls. With each antigen tested, significant changes in leukocyte migration occurred only in patients with a clinically active form of the disease and not in those receiving immunosuppressive therapy with prednisone or azathioprine. An additional series of tests with rat liver mitochondria demonstrated that the mitochondrial reaction was organ specific. It is suggested that similar tests should be performed on patients with ulcerative colitis to determine whether the leukocyte migration test could be employed to establish a differential diagnosis between these 2 conditions.

4954 AZATHIOPRINE TREATMENT IN CROHN'S DISEASE. *(E.)* Papp, J. P.; Watson, D. W.; Bull, F. E. (Univ. Michigan Med. Ctr., Ann Arbor). *Am. J. Gastroenterol.* 61(2):136-142, 1974.

After failure to respond to long trials of salicylazosulfapyridine and/or steroids, 6 patients with incapacitating Crohn's disease were treated with azathioprine (2 mg/kg/day p.o.) for 13 to 39 months. These patients consisted of 3 females and 3 males whose age at onset of the disease ranged from 12 to 22 yr. All had histories of Crohn's disease dating back more than 1 1/2 yr prior to azathioprine therapy. Crohn's disease was localized in the small intestine in 2 cases and was present in both the small and large intestine in 4. All patients were below their ideal weights, and 2 had enterocutaneous fistulas. One patient failed to respond and subsequently died of his disease. The other 5 responded during the first year of therapy with weight gain and decreases in diarrhea, pain, and incapacitation. During the 2nd and 3rd yr of treatment, 4 had resurgence of disease activity requiring surgery despite the addition of steroids. One patient had a sustained response with partial healing of fistulas, weight gain, improvement in laboratory values, and return to good health. It is suggested that therapy with azathioprine may have a place in the treatment of patients with extensive Crohn's disease when they no longer respond to the usual medical programs. The response appears to be of several months' duration in most, but is occasionally quite dramatic and prolonged in some.

4955 CROHN'S DISEASE IN SINGAPORE. *(E.)* Lee, S. K. (Dept. Pathol., Singapore). *Med. J. Aust.* 1(8):266-269, 1974.

In a 5-yr period, 6 histologically confirmed cases of Crohn's disease were diagnosed in Singapore. These patients consisted of 4 males and 2 females, aged 39-72 yr (mean 59 yr); all but 1 were permanent residents of Singapore. Of these patients, 4 were Chinese, 1 was a Sikh, and 1 Irish. Since these are probably the only fully documented and proven cases of Crohn's disease in Singapore between 1965 and 1970, the crude incidence for Chinese living in Singapore is estimated to be 0.04/100,000/yr. This rate is very low in comparison with corresponding figures from Western countries. All patients had lesions in both the large and small intestine. The lesions were mainly ulcerative with intervening areas of normal mucosa. Fibrotic strictures were found in 3 specimens; none of them had the "cobblestone" appearance. All but one of the specimens contained granulomas of the sarcoid variety. These granulomas were not present in the regional lymph nodes, which displayed reactive hyperplasia. Transmural inflammation and fissure-ulcers were other features found in histological examinations of the specimens. All patients were asymptomatic with no evidence of recurrence approximately 3 yr after the last case was diagnosed. Although all patients received drug treatment before resection of the involved intestine, none has required medication after surgery.

4956 TREATMENT OF CROHN'S DISEASE WITH AZATHIOPRINE: A CONTROLLED EVALUATION. *(E.)* Klein, M.; Binder, H. J.; Mitchell, M.; Aaronson, R.; Spiro, H. (Yale Univ. Sch. Med., New Haven, Conn.). *Gastroenterology* 66(5):916-922, 1974.

Since Crohn's disease is characterized by spontaneous remissions, a double-blind study was performed to determine whether azathioprine is effective in treating this disease. The 27 patients selected for this study were either unresponsive to other forms of medical management, had intestinal complications that would require extensive resection, or were unable to tolerate steroids because of the severity of their side effects. These patients had histories dating back 18 months to 32 yr. Only 3 patients had normal small intestines, and only 8 had normal colons. These patients were randomized either into a treatment group (3 mg/kg/day azathioprine p.o.) or a placebo group for 4 months. During the subsequent 4-month period, the treatment schedule of the 2 groups was reversed. Except that 4 patients given placebo required surgery during or immediately after the initial 4-month period, no significant difference was found between patients receiving azathioprine and controls. Improvement during azathioprine therapy was dramatic in 6 cases, but no common set of characteristics could be ascertained in these patients which would make it possible to predict in advance those who would benefit from this drug. Although some patients given azathioprine had relapses when they were placed on placebo, other patients who improved on placebo relapsed when they received azathioprine. No evidence was obtained to support the effectiveness of azathioprine in the treatment of Crohn's disease. Immunological investigations revealed that no patients treated with azathioprine demonstrated immunosuppression when appropriately challenged although some patients displayed suppression of their delayed and immediate hypersensitivity systems before drug treatment.

4957 CIRCULATING ANTIBODIES AND LEUCOCYTE MIGRATION INHIBITION TO COLON-ASSOCIATED ANTIGEN IN ULCERATIVE COLITIS AND CROHN'S DISEASE. *(E.)* Marcussen, H.; Bendixen, G. (Rigshosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):149-152, 1974.

The occurrence of circulating anticolonic antibodies against mucus-containing cells of the colonic epithelium (as detected by immunofluorescence) and cellular hypersensitivity to fetal colonic or jejunoileal mucosal extract (as detected by leukocyte migration inhibition) was compared in 26 patients with ulcerative colitis, 24 patients with Crohn's disease, and 24 patients with gastrointestinal diseases not known to be associated with bowel inflammation. The presence of circulating anticolonic antibodies was found in 19% of the patients with ulcerative colitis and in 17% of those with Crohn's disease. Inhibition of migration, using colon mucosa extract as the antigen, was found with leukocytes from 23% of the ulcerative colitis patients but with leukocytes from only 13% of the Crohn's disease patients. The apparent difference in degree of inhibition of migration rate of leukocytes from patients with these 2 different diseases was less than that found in previous work but might be explained by circumstantial unavailability of data from certain of the subjects, particularly leukocyte migration inhibition-positive cases. When jejunoileal mucosa extract was used as antigen, the incidence of inhibition of leukocyte migration in ulcerative colitis was 20%; when colon and/or jejunal extract was used, the incidence was 35%. In the patients with gastrointestinal diseases not known to be associated with bowel inflammation, tests for anticolonic antibodies and for inhibition of leukocyte migration were both negative. No case of ulcerative colitis showed co-existing humoral and cellular immunity. This fact, together with the observation that in ulcerative colitis the incidence of humoral antibody was less than that of leukocyte migration inhibition indicated a dissociation of the humoral and cellular immune reations.

4958 USE OF CHEMICALLY DEFINED DIETS IN THE MANAGEMENT OF PATIENTS WITH ACUTE INFLAMMATORY BOWEL DISEASE. *(E.)* Rocchio, M. A.; Cha, C. J. M.; Haas, K. F.; Randall, H. T. (Rhode Island Hosp., Providence). *Am. J. Surg.* 127(4):469-475, 1974.

Forty patients with acute inflammatory bowel disease, including ileocolitis, ulcerative colitis, regional enteritis, granulomatous colitis, diverticulitis, and ulcerative proctitis, were treated with chemically defined, elemental diets. The diets provided a high caloric, high nitrogen substrate with zero residue, and most were virtually fat free. Adherence to a specific protocol permitted administration of 2,000 to 5,000 calories daily for as long as 6 months without significant complication. Four of 6 patients with massive small bowel resection, 1 having only 65 cm of remaining jejunum ending in a jejunostomy, did reasonably well at home. Nitrogen balance studies in 14 of the patients and body composition studies in 7 of the patients confirmed the observation of a marked anabolic response followed by clinical improvement despite extensive gastrointestinal disease. Absorption took place in the upper part of the small bowel with minimal digestion and minimal stimulation of exocrine secretions. The ability to maintain positive nitrogen balance with enteric nutrition is a significant contribution to the treatment of patients with acute and subacute inflammatory bowel disease, obviating surgery in some and significantly reducing the operative risk in others.

4959 THE MEISSNER PLEXUS IN CROHN'S DISEASE OF THE COLON. *(E.)* Siemers, P. T.; Dobbins, III, W. O. (George Washington Univ. Med. Ctr., Washington, D.C.). *Surg. Gynecol. Obstet.* 138(1):39-42, 1974.

A light and electron microscopy study of the Meissner submucosal plexus of normal colon and of colon afflicted with Crohn's disease is presented. Tissue was obtained by rectal punch biopsy or at the time of colectomy from 7 patients with Crohn's disease. Control specimens were taken from the uninvolved margins of surgical resections of 3 patients with carcinoma of the colon and 1 patient with diverticulitis. At light microscopy, parasympathetic ganglion cells of normal colon appeared singly or in ganglia consisting of up to 7 cells and usually could be seen to be encapsulated by a rim of 1 or more thin, spindle-shaped cells. At electron microscopy, the ganglion cell or collection of cells comprising a ganglion was seen to be ensheathed by an outer layer of fibroblasts, the flattened nuclei of which paralled the curvature of the ganglion cell. A distinct, continuous, 100 micron thick basement membrane enclosed the perimeter of the ganglion and adjacent satellite cells. Double blind analysis failed to show significant distinguishing characteristics of normal ganglion cells *versus* those observed in Crohn's disease on the basis of smooth endoplasmic reticulum dilatation, mitochondrial swelling, or neurofilament concentration. Minor changes, such as axon dilatation, increased numbers of neurofilaments, and penetration of nerve fibers by plasma and mast cells were noted, however, in Crohn's disease. Further, centrioles were much more prominent in ganglion cells of Crohn's disease, a finding which supports the hypothesis that ganglion cells may undergo mitosis and explains the hyperplasia of ganglion cells previously documented in inflammatory disease of the intestine.

4960 CROHN'S DISEASE OF THE MOUTH. *(E.)* Fedotin, M. S.; Grimmett, G. M.; Shelburne, J. (Duke Univ. Med. Ctr., Durham, N.C.). *Am. J. Dig. Dis.* 19(4):385-388, 1974.

A case of Crohn's disease involving the mouth is reported. The patient, a 15-year-old white male, entered the hospital with mouth ulcers and bilateral painful masses in the buccal folds which had been present for 6 months. Prior to admission, he noted abdominal discomfort, diarrhea, and lethargy, but no hematochezia, weight loss, or fever. When his bowel symptoms improved, his mouth lesions became much smaller and less tender. An upper gastrointestinal series revealed lesions typical of Crohn's disease. The patient was treated with salicylazosulfapyridine, prednisone, and mouth washes containing hydrocortisone, nystatin, and achromycin. His bowel symptoms improved considerably and his oral lesions became less tender, much smaller, and less indurated. It is imperative that the mouth be carefully examined in every patient with Crohn's disease.

4961 BYPASS COMPARED WITH RESECTION FOR ILEAL CROHN'S DISEASE. *(E.)* Koudahl, G.; Kristensen, M.; Lenz, K. (Rigs Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(2):203-206, 1974.

The postoperative course is described in 15 patients treated with ileal bypass for Crohn's disease localized in the terminal ileum or ileum + cecum. Resection was later required in 10 of the patients since abscesses or fistulas developed in the bypassed bowel (6 cases) or Crohn's disease extended beyond the bypassed segment (4 cases). The cumulative rate of reoperation was lower among 55 patients with Crohn's disease who were treated by primary resection. Steatorrhea occurred frequently after both bypass and resection. The fecal fat excretion seemed to decrease after resection of the blind loop. Vitamin B_{12} malabsorption occurred in 75% of the cases after bypass, as well as after resection. The severity of vitamin B_{12} absorption was not influenced by resection of the blind loop. Abnormal bacterial flora in the duodenum were seen in 1 of 7 patients examined after bypass and in 1 of 9 patients after resection. Resection should always be preferred to a bypass procedure.

4962 LIFE-THREATENING HAEMORRHAGE IN CROHN'S DISEASE. *(E.)* Sunkwa-Mills, H. N. O. (Queen Elizabeth II Hosp., Welwyn Garden City, England). *Br. J. Surg.* 61(4):291-292, 1974.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Office
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-03
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington D.C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1975.

For sale by the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402. Subscription price per year in the United States, Canada, and Mexico, $29.00; foreign, $7.25 additional; and $2.25 for a single copy. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *World Medical Periodicals*, 3rd Edition, are used.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

4973 FUNCTIONAL CHARACTERISTICS OF SURGICALLY INDUCED JEJUNAL NEOMUCOSA. *(E.)* Binnington, H. B.; Sumner, H.; Lesker, P.; Alpers, A. D.; Ternberg, J. L. (Washington Univ. Sch. Med., St. Louis, Mo.). *Surgery* 75(6):805-810, 1974.

Growth of new jejunal mucosa was induced in 4 dogs by suturing an incised section of proximal duodenum to the serosal surface of the descending colon, leaving a small elliptical area of colon serosa exposed to the jejunal mucosa and lumen. Upon inspection 36 weeks postoperatively, 3 of the dogs had nearly complete coverage of the colon by neomucosa; the 4th had 50-60% coverage. Histological examination revealed that the neomucosa immediately adjacent to the original mucosa had a villous surface pattern, but the villi were generally shorter and blunter than normal. Several brush border enzymes of the neomucosa were assayed: levels of aminopeptidase, maltase, and lactase activities were normal while alkaline phosphatase, sucrase, and trehalase activities were significantly less than in the normal adjacent mucosa. Amino acids were concentrated intracellularly to the same degree by neomucosa and normal mucosa. The neomucosa was sufficiently similar to normal jejunal mucosa to warrant further studies to determine its capacity to digest and absorb food and its possible application in ameliorating severe forms of the short bowel syndrome.

4974 FOCAL AVILLOUS LESIONS IN THE GUINEA-PIG DUODENUM INDUCED BY FASTING. *(E.)* Poulsen, S. S. (Univ. Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand. (A)* 82(2):264-276, 1974.

The stomach and small intestine of 63 male guinea pigs that fasted for varying lengths of time were studied in the stereomicroscope and by conventional histological methods after periodic acid-Schiff (PAS) staining. The animals fasted for 0 (control), 12, or 18 hr and for 1, 2, 3, 4, 5, 7, or 9 days. There were no lesions in the 9 controls. In less than 24 hr, fasted animals showed superficial mucosal lesions in the duodenum, where they were most pronounced, and decreased in extent toward the proximal jejunum; more distally, no mucosal changes occurred. Within the first days they increased in extent and intensity with the duration of fasting. In some areas, the changes manifested themselves as sharply demarcated lesions in which the villi were enclosed by PAS-negative material and in which the villous structure was partially obliterated. In other areas, the central morphology was similar, but in the periphery of the lesions the apical part of all villi had been desquamated, the surface consisting merely of transverse ridges representing the common base of the villi. In addition, there were large, sharply demarcated areas in which the apices of the villi were absent throughout. Specific histological changes were as follows: no changes in some of the 12 hr and 9 day fasted animals; detachment of villi through the 5th day, with peak number at 1 day; avillous areas at 18 hr and through the entire 9 days, with high numbers at days 1-5; villi regeneration in 7 and 9 day fasted guinea pigs. The pathological reaction of avillous surface areas occurring in the guinea-pig duodenum and proximal jejunum after brief fasting may be observed also in man, elicited locally when the pH in the small intestine falls below a certain level as in patients with the Zollinger-Ellison syndrome or with duodenal ulcer.

4975 ON THE FINE STRUCTURE OF THE GALLBLADDER AND BILIARY DUCTS: V. HISTOCHEMICAL LOCALIZATION OF MUCOSUBSTANCES IN THE HUMAN GALLBLADDER EPITHELIUM. *(Ger.)* Luciano, L.; Reale, E.; Wolpers, C. (Med. Coll., Hannover, Germany). *Histochemistry* 38(1):57-70, 1974.

Cell structure and mucin synthesis and secretion were studied in gallbladders from 3 patients with cholesterosis. Small areas with no pathological changes were selected for examination. A modification of the periodic acid-Schiff (PAS) reaction was used to stain glycogen and glycoproteins, while the Alcian blue method (pH 1.2) was used to detect acid mucins. Electron microscope studies were made of thin sections stained with the periodic acid-thiocarbohydrazide (PA-TCH)-silver proteinate reaction for glycogen and glycoproteins and with the colloidal iron method for acid mucins. When examined under the light microscope, the Golgi complex gave a positive reaction only with the PAS reaction, but granules in the Golgi complex and immediately below the microvilli, together with mucins in the microvilli, gave positive reactions with both the PAS and Alcian blue methods. After drastic methylation the Alcian blue reaction became negative, suggesting that the mucins are acid (sulfated) glycoproteins. When thin sections were stained with the PA-TCH-silver proteinate method and examined under the electron microscope, silver particles were found primarily in transitional vesicles of the gallbladder epithelium and in the Golgi complex and secretion granules. The maturing surface of the Golgi complex and secretion granules reacted with colloidal iron. The contents of vesicles and tubules in the apical part of chief cells gave positive reactions with both the PA-TCH-silver proteinate and colloidal iron methods. These structures may either be involved in regeneration of the antennulae microvilares or may represent the remnants of secretion granules which have emptied through tubular processes onto the free cell surface. It remains to be seen whether mucin secreted in cholesterosis is the same as that in the normal gallbladder or whether it results from a pathological process.

4976 EPITHELIAL CELL PROLIFERATION DURING ORGANOGENESIS OF RAT COLON. *(E.)* Eastwood, G. L.; Trier, J. S. (Boston Univ. Sch. Med., Mass.). *Anat. Rec.* 179(3):303-310, 1974.

Between the 16th and 20th day of gestation, the mucosa of the colon of fetal Sprague-Dawley albino rats changed from a simple tube with a tiny lumen lined by stratified epithelium to a much more complex structure with a large lumen and well-developed crypts lined by a single layer of columnar epithelium. The number of fetal epithelial cells seen proliferating after exposure to 250 μCi ^{3}H-thymidine (i.v. into tail vein of the mother) was high during the period of organogenesis but decreased rapidly after the 20th day of gestation once the adult mucosal pattern had formed. This pattern as shown by autoradiography revealed that fetal cell proliferation was present throughout the stratified epithelium but was confined to the lower half of the colonic crypts immediately on their formation. Neonates aged 1, 10, and 20 days were also studied; and after i.p. 1.5 μCi ^{3}H-thymidine/g, autoradiographic examination showed that cell proliferation, which had sharply decreased 1-2 days before birth, remained at that lesser level up to 20 days. Thus, results indicate that between 6 days before and 2 days after birth, the colonic mucosa changes from a simple primitive stratified epithelium with very active but randomly oriented cell proliferation to a highly organized mucosa whose structure and epithelial cell proliferative pattern closely resemble that of the adult colon.

4977 CELL REGENERATION OF HUMAN GASTRIC MUCOSA. AUTORADIOGRAPHIC IN VITRO EXAMINATIONS OF GASTRIC MUCOSA BIOPSIES.

(Ger.) Castrup, H. J.; Fuchs, K.; Schiller, U. (Clin. Polyclin. Gen. Surg., Gottingen Univ., Germany). *Res. Exp. Med.* 161(4):311-320, 1973.

In vitro studies of cell proliferation were performed on gastric mucosal biopsies from male Wistar rats and male and female patients with no evidence of stomach disease. Biopsies were incubated for 2 hr in homologous (pH 7.9-8.0) and autologous plasma (pH 6.4-7.9), resp., at 37 C in an atmosphere of pure oxygen (3.2-3.5 atm). All experiments were performed between 9 and 11 a.m. Determination of the rate of ^{3}H-thymidine incorporation and the ^{3}H-labeling index in gastric mucosa from the rat showed that no decrease occurred in the rate of DNA synthesis or the number of cells synthesizing DNA under the experimental conditions employed. The mean labeling index was the same *in vitro* and *in vivo* in the rat. Autoradiographic measurements made on incubated biopsies from human gastric mucosa revealed that the mean labeling index was 10.0 ± 0.7% and the mean mitotic index, 0.8 ± 0.2%. By means of the double labeling technique, the mean duration of DNA synthesis was found to be 7.0 ± 0.6 hr, the mean generation time 71 ± 8 hr, the duration of mitosis 0.6 ± 0.1 hr, and the minimal duration of the G_2 phase, 1-2 hr. The maximal duration of the G_1 phase was calculated to be approximately 61-62 hr. With the exception of the mean generation time, which is significantly longer in man, all of these values agree well with literature values obtained *in vivo* on experiemtal animals.

4978 EFFECTS OF SOME HYPOCHOLESTEROLEMIC AGENTS ON HEPATIC ULTRA-STRUCTURE AND MICROBODY ENZYMES.

(E.) Hruban, Z.; Mochizuki, Y.; Gotoh, M.; Slesers, A.; Chou, S. F. (Dept. Pathol., Univ. Chicago, Ill.). *Lab. Invest.* 30(4): 474-485, 1974.

The effects of several drugs on body weight, plasma cholesterol, fine structure of the liver, and activities of selected hepatic microbody enzymes was investigated in Sprague-Dawley male rats fed the drugs for 6 weeks. Four groups of drugs were studied. The first group included cyclizine and its derivatives, namely, chlorcyclizine, homochlorcyclizine HCl, norchlorcyclizine, hydroxyzine HCl, and meclizine HCl; the second group, compounds affecting blood cholesterol levels, namely, 1-benzylimidazole, boxidine HCl, haloperidol, and W-1372 (N-(benzyloxy)-N-(3-phenylpropyl)-acetamide); the third, antihistaminics, including carbinoxamine maleate, chlorpheniramine maleate, chlorphenoxamine HCl, diphenhydramine HCl, tripelennamine HCl, and promethazine HCl; the fourth, a compound inhibiting formation of steroids, namely, aminoglutethimide. Each compound, mixed with Purina laboratory chow, was fed *ad libitum*. Controls received chow alone. All drugs except aminoglutethimide and W-1372 inhibited body weight gain to varying degrees. Chlorcyclizine, homochlorcyclizine, norchlorcyclizine, meclizine, 1-benzylimidazole, boxidine, and haloperidol decreased plasma cholesterol markedly. The highest catalase activity was found in liver homogenates of rats treated with 1-benzylimidazole. Highest activities of urate oxidase and of D-amino acid oxidase were found in livers of rats treated with W-1372, while aminoglutethimide reduced the activities of both these enzymes. Principle alterations in the fine structure of the hepatocytes occurred in the endoplasmic reticulum, lipid, and microbodies. Feeding of chlorcyclizine, 1-benzylimidazoline, and W-1372 was associated with hepatomegaly, alteration of rough endoplasmic reticulum, proliferation of smooth endoplasmic reticulum, accumulation of neutral lipid droplets, appearance of liposomes, proliferation of microbodies in hepatocytes, and increase in activity of the 3 microbody enzymes. Liver cells of W-1372-treated rats showed accumulation of a loose filamentous network at the membranes. This change may indicate a new cytopathologic process and is called topolysis. Perilipidic cisternae are induced by many drugs, excluding W-1372, and are believed to have a role in lipid metabolism. Hypocholesterolemia induced by boxidine and haloperidol was not associated with changes in microbodies and microbody enzymes. Ultrastructural changes induced by the various anthihistaminics showed no common pattern.

4979 OBSERVATIONS ON THE FINE STRUCTURE AND PEROXIDASE CYTOCHEMISTRY OF NORMAL RAT LIVER KUPFFER CELLS.

(E.) Wisse, E. (Lab. Electron Microscopy, Leiden, Netherlands). *J. Ultrastruct. Res.* 46(3):393-426, 1974.

An electron microscope investigation of sinusoidal lining cells in rat liver revealed that Kupffer cells have a variable but often stellate shape and a surface fuzzy coat which is visible after direct osmium fixation. Worm-like structures were restricted to

Kupffer cells, as were the annulate lamellae. The dense bodies varied in shape, diameter, and density. Kupffer cells may rest on or be inserted in, but are not continuous with, the fenestrated endothelial lining. No gaps were observed between Kupffer cells and endothelial cells. These morphological features make it possible to distinguish the Kupffer cells from other sinusoidal lining cells. The Kupffer cells did not contain droplets, glycogen particles, autophagic vacuoles, or multivesicular bodies. Only the Kupffer cells displayed a positive reaction for peroxidase in the nuclear envelope, the rough endoplasmic reticulum, and annulate lamellae after fixation for 40 sec and incubation by either perfusion or immersion. This specific staining reaction makes it possible to recognize Kupffer cells under the light microscope. Time-series incubation of Vibratome sections showed that the peroxidase reaction in Kupffer cells is sensitive to the method of fixation, H_2O_2, pH 9.0, 2×10^{-2} M AT, 10^{-2} M NaN_3, boiling, and the omission of *p*-dimethylaminoazobenzene (DAB) or H_2O_2 from the medium. No significant retardation of the reaction occurred in the presence of 10^{-2} M KCN. It is concluded that a peroxidase rather than a catalase is responsible for the reaction with DAB.

4980 MORPHOLOGICAL DIFFERENCES AMONG GASTRIC PARIETAL CELLS. *(E.)* Helander, H. F. (Dept. Anat., Univ. Umea, Sweden). *Acta Hepato-gastroenterol.* 21(1):84, 1974.

4981 EXTRANUCLEOLAR PYRONINOPHILIC SUBSTANCES IN THE LIVER CELL NUCLEI OF STARVE-REFED MICE AS REVEALED BY NONAQUEOUS NEGATIVE STAINING. *(E.)* Miyawaki, H. (Aichi Cancer Ctr., Nagoya, Japan). *J. Ultrastruct. Res.* 47(2):255-271, 1974.

4982 EFFECT OF CHOLESTYRAMINE ON TAUROCHOLATE INDUCED INJURY TO MOUSE GASTRIC MUCOSA. *(E.)* Eastwood, G. L. (U.S. Naval Hosp., Philadelphia, Pa.). *Gastroenterology* 66(4):687, 1974.

ABSORPTION—EXCRETION—TRANSPORT

4997 AMINO ACID ABSORPTION AND INCORPORATION AFTER HYPOPHYSECTOMY. *(E.)* Levitan, R.; Havivi, E.; Poppe, L.; Coleman, D. (VA West Side Hosp., Chicago, Ill.) *Am. J. Dig. Dis.* 19(6):525-532, 1974.

The effects of hypophysectomy on the intestinal uptake of ^{14}C labeled amino acids (0.5 µC) and on their incorporation into the small intestine were studied *in vitro* and *in vivo* in male albino rats of the CD strain (1 month old). Incubated segments of the small intestine from hypophysectomized rats fed *ad libitum* absorbed L-glycine at a higher initial rate and, ultimately, to a greater extent than segments from control animals when measured in a time-course experiment 5 days following surgery. The enhanced uptake due to hypophysectomy was observed with amino acid concentrations up to 20 mM for both L-glycine and L-leucine and was essentially maximal at concentrations of 10-15 mM. Five days after surgery, the absorption of L-leucine and that fraction of absorbed leucine present in the cell sap of the tissue rose from approximately 62% in the sham-operated control intestinal segments to 85% in the tissue of the hypophysectomized groups. Similar results were obtained with L-glycine, DL-methionine, and DL-ornithine during this early, postsurgical period. Four to five days following ablation, L-leucine uptake became significantly less than the essentially unchanged value seen in the sham-operated controls. In general, reduced incorporation of the labeled amino acids into protein was obtained both *in vivo* in isolated intestinal loops and *in vitro*. Weight gained by sham-operated rats exceeded that gained by hypophysectomized rats in the pair-fed group. These findings show a divergent response to hypophysectomy as regards amino acid uptake by rat intestine, an enhanced uptake 4-5 days following surgery and a depressed uptake subsequently.

4998 TRANSDUCTAL FLUXES OF ANIONS IN THE RAT PANCREAS. *(E.)* Mangos, J. A.; McSherry, N. R.; Nousia-Arvanitakis, S.; Schilling, R. F.; Wagner, V. (Univ. Wisconsin Med. Sch., Madison). *Proc. Soc. Med. Exp. Biol.* 146(1):321-328, 1974.

The effect of i.v. secretin (0.5 units/min) on the transductal fluxes of anions were studied in the pancreas of male, albino Sprague-Dawley rats. The stimulation of pancreatic secretion with pilocarpine was performed by injecting the drug i.v. (0.2 mg/100 g). During stimulation of the rat pancreas with secretin, the Cl^- concentrations in the pancreatic juice were elevated at high flow rates approaching those found in the acinar fluid of the gland. With decreasing flow rates toward prestimulation levels, a gradual decrease in the Cl^- concentrations to approximately 70.0 mEq/liter was observed. The change in the HCO_3^- concentrations were in the opposite direction to those of Cl^-. During stimulation of rat pancreatic secretion with pilocarpine, the Cl^- concentration in the pancreatic juice did not change with changes in the flow rates and remained at the mean level of approximately 120.0 mEq/liter, identical to the concentrations of Cl^- found in the acinar fluid during this form of secretory stimulation. Similarly, HCO_3 concentrations remained at the level of approximately 29.0 mEq/liter, again identical to acinar fluid concentrations. During i.v. stimulation of the rat pancreas with cholecystokinin-pancreozymin (0.3 units/min), there were no net transductal fluxes of anions, and the anionic composition of the final pancreatic juice was identical to that of the primary fluid secreted by the gland. The results show that transductal fluxes of anions against concentration gradients occur in the duct system of the rat pancreas during stimulation of secretion with exogenous secretin injected i.v. These fluxes cannot be demonstrated in the unstimulated and in the cholecystokinin-pancreozymin or pilocarpine stimulated pancreas.

4999 INFLUENCE OF VASOPRESSIN AND TOPICAL BILE SALTS ON THE GASTRIC MUCOSAL BARRIER OF THE SUBHUMAN PRIMATE. *(E.)* Ritchie, W. P., Jr. (Walter Reed Army Inst. Res., Washington, D.C.). *Surgery* 75(6):853-860, 1974.

The effect of mucosal ischemia alone and in combination with topically applied bile salts on the gastric mucosal barrier properties was studied in 4 rhesus monkeys (*Macaca mulatta*). The animals were prepared with internally drained, vagally denervated fundic pouches. Each pouch was cannulated and exposed first to acid test solution alone (80 mM HCl, 80 mM NaCl, 2 g/liter polyethylene glycol) and then to acid test solution containing 10 mM sodium taurocholate. Electrical potential difference was continuously monitored, and the net fluxes of H_2O, H^+, and Na^+ were assessed at 15-minute intervals with acid test solution and acid test solution plus sodium taurocholate (10mM) during the continuous intra-arterial infusion of 0.9% NaCl into the celiac axis and during the infusion of the celiac axis with vasopressin, (0.05 U/kg/min). With acid test solution alone, mucosal ischemia markedly reduced net Na^+ and H_2O flux and significantly impaired the ability of the mucosa to maintain electrical gradients, findings more consistent with inhibition of active transport processes and contraction of the extracellular space than with alterations in mucosal permeability. With taurocholate acid test solution, mucosal ischemia did not further alter the potential difference *versus* acid test solution alone and did not increase net H^+ flux *versus* the non-ischemic mucosa. It is concluded that in the subhuman primate, ischemia *per se* does not significantly affect gastric mucosa permeability and does not significantly enhance permeability changes induced by the topical application of 10mM sodium taurocholate.

5000 STUDIES ON ACTIVE ABSORPTION OF VITAMIN B_{12} BY ISOLATED RAT ENTEROCYTES. *(Fr.)*

Carrera, G.; Mitjavila, S.; Derache, R. (Res. Group Toxicol. Foods, Beverages, INSERM, Toulouse, France). *Biol. Gastroenterol. (Paris)* 7(1):43-51, 1974.

Isolated cells were prepared from rat ileum by treatment with physiological saline containing 2.5 mM ethylenediamine tetraacetic acid (EDTA) for 25 min at 7 C. After washing several times with Krebs-Ringer bicarbonate (pH 7.7) to remove the EDTA, calcium was added to the medium and cells were resuspended in Krebs-Ringer bicarbonate containing 1% glucose. Vitamin B_{12} absorption in these cells was measured by incubating them in a Warburg apparatus at 37 C in the presence of ^{57}Co-labeled vitamin B_{12} and rat gastric juice containing active or thermally inactivated intrinsic factor. In the absence of intrinsic factor vitamin B_{12} absorption was not eliminated but amounted to almost 60% of that occurring in the presence of active gastric juice. This phenomenon is attributed to passive binding of the vitamin. Active absorption, which occurred in the presence of intrinsic factor, was significantly inhibited by the addition of ouabian (2 mM/liter), phloridizine (1 and 2 mM/liter), and 2,4-dinitrophenol (1 mM/liter) to the medium. Although passive binding of vitamin B_{12} increased in a dose-dependent fashion when ethanol (5 and 10 g/liter) was added to the medium, ethanol significantly decreased active vitamin B_{12} absorption. Ethanol may favor penetration of the vitamin into membrane lipoprotein, thus increasing passive binding. The decrease in active vitamin B_{12} absorption suggests that ethanol interferes with enzyme systems responsible for active transport of vitamin B_{12}.

5001 SUCROSE AND HYPERLIPIDAEMIA. II. THE RELATIONSHIP BETWEEN THE RATES OF DIGESTION AND ABSORPTION OF DIFFERENT CARBOHYDRATES AND THEIR EFFECTS ON ENZYMES OF TISSUE LIPOGENESIS.

(E.) Naismith, D. J.; Rana, I. A. (Dept. Nutr., Queen Elizabeth Coll., London, England). *Nutr. Metab.* 16(5):285-294, 1974.

Weanling Sprague-Dawley rats were fed, for 50 days, diets containing starch, sucrose, maltose, fructose or glucose. No differences were found among the different groups in the rates of growth or in food intakes. The concentration of triglycerides in the plasma was raised by more than 50% when the dietary carbohydrate was presented in the form of monosaccharides or disaccharides. When compared with the effects of the high-starch diet, diets containing the sugars promoted a substantial, and similar, rise in plasma lipids. Hepatic lipogenesis was increased by all the sugars, sucrose and maltose having an equal effect. Lipogenesis in adipose tissue was, however, depressed by feeding sucrose or fructose. Diets containing sucrose, maltose or fructose stimulated a significant rise in concentration of cholesterol in the plasma. In rats fed sucrose or maltose, the activity of pyruvate kinase was doubled when compared with the value for rats fed starch. Fructose induced a 4-fold increase, whereas glucose had least effect. The sugars were digested and absorbed much more rapidly than was starch. The hyperlipidemic effect of sucrose can be explained primarily on the basis of its rapid rate of hydrolysis and absorption, and any differences existing between the metabolism of glucose and fructose are of secondary importance.

5002 EFFECT OF FREE AND CONJUGATED BILE ACIDS ON NET WATER, ELECTROLYTE, AND GLUCOSE MOVEMENT IN THE PERFUSED HUMAN ILEUM. *(E.)*

Krag, E.; Phillips, S. F. (Mayo Clin. Fdn., Rochester, Minn.). *J. Lab. Clin. Med.* 83(6):947-956, 1974.

Perfusion studies were performed in 8 healthy volunteer subjects (21 to 45 yr) to test whether the secretory effect of bile acids, previously shown for the colon and the jejunum, was present in the ileum. A perfusion system with a proximal occlusive balloon (and aspiration of upper intestinal secretions) was used; isotonic test solutions contained bile acids. Fluid movement was measured by changes in the concentration of polyethylene glycol. The following bile acids were used: glycochenodeoxycholic acid, glycodeoxycholic acid, chenodeoxycholic acid, deoxycholic acid, glycolic acid, and cholic acid. Free and glycine-conjugated dihydroxy compounds and free trihydroxy bile acid inhibited net fluid and electrolyte absorption and, at higher concentrations, evoked secretion of water and electrolytes. The free dihydroxy bile acids were especially potent. The conjugated trihydroxy bile acid glycocholic acid had no effect on ileal absorption. Glucose absorption continued despite fluid secretion, but its rate decreased during perfusion with free dihydroxy bile acids. As much as 70% of perfused bile acids were absorbed from the ileum. Water movement was closely correlated to the net movements of sodium, potassium, chloride, and bicarbonate. When water was absorbed, electrolytes were absorbed, and when fluid was secreted, all ions were secreted. Minor degrees of abdominal cramps, vomiting, and diarrhea were noted by 3 subjects during perfusion of glycochenodeoxycholic or chenodeoxycholic acid. These symptoms may be related to an effect of unabsorbed bile acids entering the colon where they can induce water secretion and diarrhea. The results indicate that physiologic concentrations of dihydroxy bile acids influence salt and water transport in the human ileum. It is proposed that this effect of bile acids may influence the consistency of ileal contents postprandially.

5003 ACTIVE AND PASSIVE BILE ACID ABSORPTION IN MAN. PERFUSION STUDIES OF THE ILEUM AND JEJUNUM. *(E.)* Krag, E.; Phillips, S. F. (Mayo Clin., Fdn., Rochester, Minn.). *J. Clin. Invest.* 33(6):1686-1694, 1974.

Absorption of the major human bile acids was investigated in 12 healthy volunteers by steady state perfusion of the distal ileum in 112 studies and of the proximal jejunum in 48. Use of a randomized order of 4 different bile acid perfusions on 1 day of study and also up to 4 consecutive days in a subject allowed important comparisons of data from the same individual. Chenodeoxycholic acid was absorbed faster than glycochenodeoxycholic acid in the ileum. At most concentrations, the passive component of chenodeoxycholic acid absorption was quantitatively important in the ileum; whereas for glycochenodeoxycholic acid, the active component predominated. Taurocholate had the highest apparent maximal transport velocity in the ileum and was absorbed more rapidly than glycochenodeoxycholate. In the jejunum, passive permeability to bile acids was twice that of the ileum, and the permeabilities to free and glycine-conjugated chenodeoxycholate were in the same ratio as in the ileum (9:1). Jejunal permeability to chenodeoxycholic acid was 3 times that of cholic acid. Variation of intraluminal pH by up to 1.4 units did not influence jejunal uptake of free bile acids. These results provide a basis for estimation of intestinal reabsorption of bile acids in intact man.

5004 INTESTINAL FRUCTOSE ABSORPTION IN ETHANOL-TREATED RATS. *(It.)* Ghirardi, P.; Marzo, A.; Grassetti, S. (Inst. Biol. Chem., Univ. Milan, Italy). *Boll. Soc. Ital. Biol. Sper.* 49(11):629-632, 1973.

Fructose absorption was measured in the small intestine of Sprague-Dawley rats fed *ad libitum* and given 4 g/kg/day ethanol, p.o. through a stomach tube, for 2, 7, and 20 days. Untreated rats served as controls. Experiments were performed after a 5 hr fast in controls and 5 hr after the last dose of ethanol in treated rats. At laparotomy, 5 ml of a 20% fructose solution (1 g) was placed in the small intestine which was ligated at the top of the duodenum and at the ileocecal valve. After 1 hr the solution was removed and fructose was determined photometrically by the 3-indolacetic acid reaction. In contrast to glucose absorption, which was reduced in previous experiments on ethanol-treated rats, ethanol had no effect on fructose absorption. This is attributed to the passive, rather than active, absorption of fructose due to its lack of an alcoholic hydroxyl group on C2 in both the pyranose and furanose forms.

5005 EVIDENCE FOR ACTIVE TRANSPORT OF THE DIPEPTIDE CARNOSINE (β-ALANYL-L-HISTIDINE) BY HAMSTER JEJUNUM IN VITRO. *(E.)* Matthews, D. M.; Addison, J. M.; Burston, D. (Westminster Med. Sch., London, England) *Clin. Sci. Mol. Med.* 46(6):693-705, 1974.

The characteristics of intestinal transport and hydrolysis of carnosine (β-alanyl-L-histidine) were studied in rings of everted hamster jejunum *in vitro.* During incubation with carnosine, large amounts of intact peptide appeared in the intestinal wall, accompanied by small amounts of the constituent free amino acids. Although there was some extracellular hydrolysis, these amino acids were almost entirely derived from intracellular hydrolysis of the peptide. Incubation in L-alanyl-L-histidine resulted in uptake of the constituent free amino acids without the appearance of intact peptide in the intestinal wall. Total uptake of β-alanine (both peptide-bound and free) and total uptake of histidine were greater from a low concentration (1 μM/ml) of carnosine than uptake of these amino acids from the equivalent amino acid mixture. At a high concentration of carnosine (10 μM/ml), total uptake of β-alanine was greater from the peptide than from the equivalent amino acid mixture, but total uptake of histidine was less. At this concentration, total uptake of β-alanine plus total uptake of histidine from the peptide was approximately the same as from the amino acid mixture. Uptake of carnosine by jejunal rings was the result of a saturable process. Intact carnosine was concentrated in the intestinal wall, the concentration ratio between intracellular fluid and incubation medium being up to 3.4/1. Uptake of carnosine was reduced by anoxia, metabolic inhibitors, and replacement of medium Na^+. The data suggest that Na^+-dependent active transport is involved in the uptake of carnosine by hamster jejunum *in vitro.*

5006 HEREDITARY FRUCTOSE INTOLERANCE. ANIMAL MODEL: SUSTAINED INTRAPORTAL INFUSION OF RATS WITH FRUCTOSE. *(E.)* Phillips, M. J.; Yu, D. T.; Burch, H. B. (Dept. Pathol., Univ. Toronto, Canada). *Am. J. Pathol.* 75(3):591-594, 1974.

An experimental model for use in the study of hereditary fructose intolerance in man is described and discussed. Since fructose administration to rats, either i.v. or i.p., results in hepatic retention of metabolites, especially fructose-1-phosphate, and a transient drop in hepatic ATP levels, this procedure was followed here in male Wistar rats. Continuous infusion of concentrated (40% and 10%) fructose solution *via* mesenteric vein catheter did induce sustained accumulation of fructose-1-phosphate and marked reduction in ATP. The rapid phosphorylation of fructose tied up the available ATP and phosphate ions, setting the stage for degradation of adenine nucleotides, one of these being inosine monophosphate which inhibits aldolase B. Therefore, secondarily there was further accumulation of fructose-1-phosphate. Concomitant with these biochemical changes, alterations in cellular structure occurred: hyaloplasmic rarefaction, segmental degranulation of rough endoplasmic reticulum with formation of pleomorphic membranous whorls, nodular aggregation of smooth endoplasmic reticulum, and simplification and decrease in size of the Golgi apparatus. Under similar experimental conditions, rats infused with other hexoses showed no such lesions and no alterations in hepatic ATP and fructose-1-phosphate levels. As seen here, sustained fructose loading in rats induces acute hepatocellular lesions that are the morphologic and biochemical counterparts of those seen in hereditary fructose intolerance in man. Therefore, this experimental model can be used to study the pathogenesis and biochemical pathology of hepatic subcellular lesions in this disorder.

5007 IN VIVO CALCIUM TRANSPORT BY RAT SMALL INTESTINE AFTER MASSIVE SMALL BOWEL RESECTION.

(E.) Urban, E.; Pena, M. (Univ. Texas Med. Sch., San Antonio). *Am. J. Physiol.* 226(6):1304-1308, 1974.

Because long-term survival and well-being after extensive small bowel resection largely depend on the absorptive capacity of the remaining intestine, this study was designed to investigate adaptation of calcium transport in the small intestine after such surgery in male albino Sprague-Dawley rats. Segments of 50 cm were excised from either the proximal or distal small bowel and the cut ends sutured together to maintain continuity of the lumen. After 6-7 weeks, calcium transport changes were assesed *in vivo* on the basis of: (1) mucosal transport specific activity (lumen-to-plasma flux and absorption/g dry mucosa); and (2) segment transport capacity (lumen-to-plasma flux and absorption/cm segment length). Calcium was supplied by a 2 ml/min perfusion of ligated 10 cm segments of duodenum, midgut and ileum for 2 hr with 10 ml of recycled solutions containing 3.4 mM ^{40}calcium as calcium chloride and approximately 0.2 μC/ml of tracer ^{45}calcium. Proximal resection resulted in significant mucosal growth in all three segments: (A) duodenal transport specific activity decreased, but mucosal mass increased; therefore segment transport capacity remained unchanged; (B) midgut transport specific activity increased and mucosal mass increased maximally; hence segment transport capacity more than doubled; and (C) ileal transport specific activity remained unchanged; thus segment transport capacity mirrored the increased mucosal mass. Distal resection resulted in no mucosal growth in all 3 segments: (A) duodenal transport specific activity fell, hence segment transport capacity decreased; (B) the midgut showed no change in either transport specific activity or segment transport capacity; and (C) ileal transport specific activity increased and segment transport capacity rose correspondingly. One most striking finding was that the maximal adaptation of segment transport capacity occurred in the midgut after proximal resection. Another striking result was the decrease in duodenal mucosal transport specific activity after each type of resection compensated by mucosal growth only after proximal excision. In man, previous investigations found that the segment distal to the duodenum was more sensitive to factors controlling calcium absorption under normal physiological conditions. Perhaps the same holds true under the abnormal conditions after massive intestinal resection. In general, the mechanisms by which calcium transport adaptations occurred in these findings remain to be defined.

5008 INTESTINAL ABSORPTION OF PROSTAGLANDIN $F_{2\alpha}$, 15(S)-15-METHYL PROSTAGLANDIN $F_{2\alpha}$ AND THEIR METHYL ESTERS IN THE DOG.

(E.) Robert, A.; Magee, W. E.; Miller, O. V.; Nezamis, J. E. (Upjohn Co., Kalamazoo, Mich.). *Biochim. Biophys. Acta* 348(2):269-278, 1974.

Radioactive prostaglandins were introduced *in vivo* into the lumen of intact jejunal loops of male mongrel dogs; and venous blood, collected from the segments at 5 min intervals for a 60 min period, was analyzed for absorbed drugs and metabolites. At least 10^7 cpm of each radioactive compound was used for each dog in a total of 2.0 mg. (A) Absorption of [9-^{3}H]-Prostaglandin $F_{2\alpha}$: After administration of this compound or its methyl ester, from 8-18% of initial radioactivity accumulated in the blood in 60 min. However, both compounds were extensively metabolized in the intestinal mucosa: (1) less than 0.3% of the administered dose of prostaglandin $F_{2\alpha}$ was recovered from the blood as the intact compound; and (2) following administration of the methyl ester, up to 1.7% of the dose was found in the blood as unesterified prostaglandin $F_{2\alpha}$. (B) Absorption of 15(S)-15-methyl-prostaglandin $F_{2\alpha}$: A methyl group at carbon-15 of the prostaglandin molecule slowed down intestinal absorption considerably. Thus, when this methylated compound was given, from 0.8-1.2% of the radioactivity of the administered dose accumulated in the blood. For the more readily absorbed methyl ester, 2.4-4.7% radioactivity reached the blood. In both cases, 25-50% of plasma radioactivity appeared as free acid (blood levels of 0.3-4.2% of the dose). Because of mucosal and plasma esterase activity, very little ester appeared in the blood. Since a methyl group at carbon-15 blocks the action of prostaglandin dehydrogenase without preventing other degradative reactions, intestinal administration of 15(S)-15-methylprostaglandin $F_{2\alpha}$ results in appreciable blood levels of the intact compound. Thus, the 15(S) compounds, which are more active than the parent prostaglandins in antifertility tests and as gastric antisecretory agents, offer an opportunity to evaluate intestinal absorption more readily. Increasing the lipophilicity of the compounds by esterification of the carboxyl group also affects the intestinal absorption.

5009 REVERSED NET WATER FLUX IN FROG GASTRIC MUCOSA IN THE ABSENCE OF AN APPLIED OSMOTIC GRADIENT. *(E.)* Villegas, L.; Sananes, L. (Biophys., Biochem. Ctr., Venezuelan Inst. Sci. Invest., Caracas). *Am. J. Physiol.* 226(6):1338-1343, 1974.

Results of studies on the influence of serosal and mucosal extracellular compartments of gastric mucosa on water movement and the effects of solution viscosity on the net water and ionic fluxes are presented here. Gastric mucosa stripped from the excised stomach of *Rana pipiens* was tested for the effects of dextran (10 mM) on the net water flux, potential difference, net ion transport, acid secretion, and conductance. The viscosity of these dextran solutions measured 4.7 times greater than that of the nutrient solution alone and that of water. Dextran simultaneously applied at the serosal and mucosal surfaces inhibited the net water flux, reduced the net ion transport and secretion by 27%, and reduced the conductance by 38%. Applied at the mucosal surface only, dextran produced no changes in net water flux, net ionic transport and secretion, and conductance. When dextran was used on the serosal surface only, there was a reversal of net water flux, a reduction by 17% of ionic transport and secretion, and reduction of conductance by 29%. It is believed that the effects on water filtration and ionic conductance (when the viscosity of solutions is increased by 4.7 upon the addition of dextran) must change the composition of the serosal extracellular space content. Therefore, the effect of this change in composition on the net water flux is considered as evidence of the role of the extracellular space in regulating the net volume flux.

5010 THE INFLUENCE OF BLOOD FLOW ON THE PHLORIZINE-INSENSITIVE AND SENSITIVE GALACTOSE ABSORPTION IN RAT JEJUNUM. *(E.)* Lichtenstein, B.; Winne, D. (Pharmacol. Inst., Univ. Tubingen, Germany). *Naunyn Schmiedebergs Arch. Pharmacol.* 282(2):195-212, 1974.

Jejunal loops of anesthetized male Wistar rats were perfused with buffered solutions (pH 6.8) containing D-galactose in 2 concentrations: below (100 μM) and above (100 mM) blood sugar concentration. At constant intermediate blood flow, the appearance rate and disappearance rate decreased with time. A decrease of the blood flow rate from about 1.9 to about 0.3 ml/min/g diminished both appearance and disappearance rates. Increasing the blood flow from about 0.3 to about 1.0 ml/min/g did not increase the absorption rates. In fact, a slight decrease was noted. In the presence of phlorizin (2 mM) the absorption rates and the tissue accumulation of galactose were reduced. At constant intermediate blood flow, the appearance and disappearance rate increased with time. A decrease of the blood flow rate from about 1.8 to about 0.3 ml/min/g diminished the appearance rate. An increase in blood flow rate from 0.3 to 1.8 ml/min/g increased the appearance rate in contrast to the experiments without phlorizin. Therefore, the different blood flow dependence of the intestinal absorption observed with actively transported substances can be attributed to their nonpassive component.

5011 REVERSAL OF COLONIC NET ABSORPTION TO NET SECRETION WITH INCREASED INTRALUMINAL PRESSURE. *(E.)* Bury, K. D.; Mc Clure, R. L.; Wright H. K. (Yale Univ. Sch. Med., New Haven, Conn.). *Arch. Surg.* 108(6):854-857, 1974.

In Wistar strain rats, the intraluminal pressure of 10 cm colonic loops was raised by *in vivo* perfusion from control levels of 4 cm saline to experimental levels of 30 cm for 1 hr in order to measure effects on net water, sodium, and unidirectional sodium movement. Nonabsorbable polyethylene glycol (1%) was used as a water marker, while ^{24}sodium (5 μC/liter) measured sodium movement; both were perfused with saline. The equilibration period of 1 hr showed absorption of both water (0.34 ml/cm/hr) and sodium (44.9 Eq/cm/hr). With increase of intraluminal pressure to over 30 cm saline, a rapid reversal of both water and salt from net absorption to net secretion was seen at 15 min with continued rise in secretion over 1 hr, even though intracolonic pressure was kept stable. Increased movement of sodium from blood to lumen was the main cause for the observed net secretion. It is suggested that an increased intraluminal pressure is transmitted across the mucosa, causing an increase in mucosal interstitial pressure with a diffusion of isotonic saline into the lumen in response to this gradient. However, upon release of the intraluminal pressure although recovery was progressive, net secretion of both sodium and water was still present after 45 min. Unidirectional sodium movement during the control period demonstrated bidirectional movement of sodium, with lumen-to-blood movement exceeding blood-to-lumen With increased intraluminal, pressure, insorption dropped while exsorption increased. At all times, there was a significant correlation between water and sodium movement, and net movement whether absorption or secretion was isotonic. This series of events can best be explained by a concept of mainly active transport of sodium from lumen to blood while movement in the reverse direction is a filtration or diffusion phenomenon dependent on the creation of osmotic gradients. This study particularly underline the magnitude of fluid loss that can be caused by significant increases in intracolonic pressure and emphasizes that this loss continues for some time after the relief of the obstruction. The fluid shift is isotonic and similar in electrolyte composition to plasma. Results here also point out the danger in delay of relief of obstruction as the alteration in fluid dynamics is a progressive one, and recovery of function is probably much slower in cases of obstruction.

MOTILITY

5043 DIFFERENTIAL RESPONSES OF THE CANINE GASTRIC CORPUS AND ANTRUM TO ELECTRIC STIMULATION. *(E.)* Kelly, K. A. (Mayo Fdn., Rochester, Minn.). *Am. J. Physiol.* 226(1): 230-234, 1974.

Silver wire electrodes, bipolar for stimulation (interelectrode distance of 5 mm) and monopolar for recording electric activity concurrent with stimulation, were implanted on the anterior all of the gastric corpus and antrum of 4 dogs. After a 2-week recovery period, the fasted, conscious dogs were given electric stimuli intermittently during 3 to 4 months. Pacesetter potentials were generated at both corporal and antral sites of stimulation. Since gastric smooth muscle is spontaneously active, the threshold for electric generation of pacesetter potential was determined by suppressing the natural pacemaker and gradually drecreasing the strength or duration of a suprathreshold stimulus, rather than by gradually increasing the strength of a subthreshold stimulus in the conventional way. As the strength of the stimulus was increased, a shorter duration of stimulation was required to reach threshold; strength *versus* duration curves in both the corpus and antrum were equilateral hyperbolas. However, the antrum had a smaller rheobase, a briefer chronaxie, and a shorter refractory period than the corpus and could be driven to faster frequencies by stimulation. These characteristics of the antrum, coupled with its slower intrinsic pacesetter potential frequency, facilitate entrainment of the distal stomach by the corporal pacemaker.

5044 ADRENERGIC RECEPTORS OF RAT ESOPHAGEAL SMOOTH MUSCLE. *(E.)* Buckner, C. K.; Christopherson, R. C. (Sch. Pharm. Univ. Wisconsin, Madison). *J. Pharmacol. Exp. Ther.* 189(2):467-475, 1974.

Adrenergic receptors in muscularis mucosa from the body of the rat esophagus have been investigated by using adrenergic agonists and competitive antagonists. Neither isoproterenol nor phenylephrine produced contraction of the tissue. After contraction induced by carbachol, both adrenergic agonists produced dose-dependent relaxation. Isoproterenol was approximately 1000 times more potent than phenylephrine, and only the former agonist relaxed the tissue to base-line levels. Cocaine potentiated the effects of phenylephrine; tropolone did not significantly alter the effects of isoproterenol. Phentolamine did not antagonize the relaxation produced by either agonist. Propranolol blocked effects of both agonists to a similar degree although it was approximately 1/1000 as potent as in other tissues. Sotalol[4-(2-isopropylamino-1-hydroxyethyl)methanesulfonanilide HCl] and practolol[4(2-hydroxy-3-

sopropylaminopropoxy)acetanilide HCl] were not
otent antagonists of the responses. The potency
ifferences between enantiomers of isoproterenol
nd trimetoquinol[1-(3',4',5'-trimethoxybenzyl)-
,7-dehydroxyl-1,2,3,4-tetrahydroisoquinolone HCl]
ere (in log units) 2.53 and 1.66, resp. These
alues are similar to those previously reported in
uinea-pig atrium and trachea and suggest a simi-
arity of receptor sites for these agonists in the
tissues. The results indicate that α-adrenergic
eceptors are not present in rat esophageal mus-
ularis mucosa and that relaxation in response to
drenergic agonists is due to activation of β-adrener-
ic receptors. Resistance to β-receptor antagonists
eed not invoke a postulate of different β receptor
ypes.

5045 INTRACELLULAR CYCLIC AMP LEVEL AND INTESTINAL SMOOTH MUSCLE RELAXATION. *(E.)*

Inatomi, N.; Takayanagi, I.; Uchida, M.; Takagi, K. (Fac. Pharm. Sci., Univ. Tokyo, Bunkyo-ku, Japan). *Eur. J. Pharmacol.* 26(1):73-76, 1974.

The intracellular level of cyclic AMP in the taenia from the guinea pig cecum was significantly increased by isoproterenol in a dose-dependent manner. Papaverine also increased the intracellular cyclic AMP level, but a synthetic antispasmodic agent, Aspaminol (1,1-diphenyl-3-piperidinobutanol hydrochloride) did not modify it. The results suggest that there are 2 mechanisms for the so-called papaverine-like actions. The increase in the intracellular cyclic AMP concentration produced by isoproterenol was prevented by propranolol. Papaverine caused relaxation but isoproterenol did not in taenia depolarized by KCl. This difference can be explained by the observation that the intracellular cyclic AMP level in the KCl-depolarized taenia is increased by papaverine but not by isoproterenol.

5046 FORCE-VELOCITY CHARACTERISTICS OF ESOPHAGEAL MUSCLE: EFFECT OF ACETYLCHOLINE AND NOREPINEPHRINE. *(E.)*

Cohen, S.; Green, F. (Univ. Pennsylvania Hosp., Philadelphia). *Am. J. Physiol.* 220(5):1250-1256, 1974.

A study was made of the effect of adrenergic and cholinergic agents on the force-velocity characteristics of the neurally mediated "off response" of the circular smooth muscle in the esophagus and lower esophageal sphincter of the opossum *in vitro*. Isotonic and isometric recordings were used to obtain the velocity of shortening and force, resp., during superfusion of acetylcholine and norepinephrine. All measurements were made with smooth muscle at its length of optimal tension development. To determine the effect of acetylcholine and norepinephrine on muscle contractility studies were performed using a 1.0-mM calcium Krebs solution. The maximum velocity of shortening and the peak force of esophageal muscle was 2.7 mm/sec and 8.2 g resp., at 1.0 mM calcium. Acetylcholine (10^{-5} M) increased the maximum velocity to 6.5 mm/sec and the peak force to 14.8 g. Norepinephrine (10^{-5} M) increased the maximum velocity to 6.5 mm/sec and the peak force to 15.4 g. The lower esophageal sphincter muscle responded similarly. It is concluded that both acetylcholine and norepinephrine significantly increase the maximum velocity and peak force of circular smooth muscle in the esophagus and lower esophageal sphincter, during the neurally mediated off response.

5047 MODIFICATION OF INTESTINAL STIMULATORY EFFECTS OF 5-HYDROXYTRYPTAMINE BY ADRENERGIC AMINES, PROSTAGLANDIN E_1 AND THEOPHYLLINE. *(E.)*

Grubb, M. N.; Burks, T. F. (Univ. Texas Med. Sch., Houston). *J. Pharmacol. Exp. Ther.* 189(2):476-483, 1974.

Isolated intestinal segments in dogs were perfused *via* the vasculature with Krebs-bicarbonate solution with or without drugs which depress motility: adrenergic amines, prostaglandin E_1, and theophylline. The excitatory agonists tested were 5-hydroxytryptamine, bethanechol and dimethylphenylpiperazinium iodide. Isoproterenol (1 and 5 μg/ml) shifted the 5-hydroxytryptamine dose-response curve to the right but did not affect intestinal contractions produced by the cholinergic agonists, bethanechol and dimethylphenylpiperazinium. Prostaglandin E_1 (1 μg/ml) did not alter responses to bethanechol, but caused a slight decrease in responses to dimethylphenylpiperazinium. Prostaglandin shifted the 5-hydroxytryptamine dose-responsive curve to the right. Theophylline (180 μg/ml) produced a shift to the right in the dose-response curve only for 5-hydroxytryptamine. Norepinephrine (0.1 and 0.2 μg/ml) produced shifts to the right in dose-response curves for dimethylphenylpiperazinium and 5-hydroxytryptamine but not for bethanchol. Methoxamine (10 and 50 μg/ml caused effects similar to those produced by norepinephrine. These data indicate that β-adrenergic agonists, prostaglandin E_1, and theophylline, which have in common the ability to increase intestinal cyclic AMP, antagonize motility responses to 5-hydroxytryptamine but have little or no effect on motility responses to cholinergic agonists. The effect of norepinephrine on dimethylphenylpiperazinium can be explained in terms of α-adrenergic receptor actions since methoxamine had similar effects on dimethylphenylpiperazinium responses. It is hypothesized that 5-hydroxytryptamine produces contraction of intestinal smooth muscle by somehow lowering intracellular levels of cyclic AMP or by blocking cyclic AMP inhibitory effects.

5048 STUDIES ON THE INTESTINAL ACTIONS OF TYRAMINE. *(E.)*

Heilman, R. D.; Lum, B. K. B. (Med. Coll. Wisconsin, Milwaukee). *Med. Biol.* 52(1):39-47, 1974.

The response to varying concentrations of tyramine (1600, 3200, and 6400 μg) in the isolated rabbit jejunum bathed in Ringer's solution is usually biphasic and consists of an initial stimulation followed by a slight relaxation but this relaxation is minimal in comparison to that produced by norepinephrine. Blockade of the stimulant action of tyramine by 500 μg methysergide added to the 50 ml organ bath did not enhance the relaxation. The relaxation produced by tyramine was abolished by 2 mg/kg i.m. reserpine pretreatment and was augmented by the presence of norepinephrine (50-100 μg) in the bathing medium. The relaxation thus appears to be due to a release of catecholamines by tyramine. However, the maximum relaxation produced by tyramine, even in the presence of 1-4 μg/liter norepinephrine was only about 33% of the maximum produced by norepinephrine alone. Tyramine antagonized the relaxation produced by 0.5-8.0 μg norepinephrine, 10-100 μg methoxamine, 0.2-1.0 μg isoproterenol, and 60 μg nitroglycerin. Quantitative studies suggest that this blocking action represents a major factor in the failure of tyramine to produce a maximum relaxation equal to that produced by norepinephrine. The relaxation produced by tyramine was also enhanced when the isolated jejunum was bathed in dog blood which contained relatively low concentrations of catecholamines. Enhancement of the response to tyramine by the blood appeared to be dependent on other factors.

5049 THE STUDY OF GUINEA-PIG GALLBLADDER REACTIVITY AFTER PGE$_1$ STIMULATION. *(E.)*

Stasiewicz, J.; Szalaj W,; Gabryelewicz, A. (Med. Acad., Bialystok, Poland) *Pol. J. Pharmacol. Pharm.* 26(1/2):249-252, 1974.

The effect of prostaglandin E$_1$ (PGE$_1$) on the reactivity of the isolated guinea pig gallbladder was investigated. 'PGE$_1$ (50-100 ng/ml) induced contractions in the gallbladder which resembled those seen following the administration of cholecystokinin. Stimulation of the β-adrenergic receptors by isoproterenol (0.5 ng/ml) significantly diminished the contractions induced by PGE$_1$; after β-adrenergic blockade by propranolol (0.1 μg/ml), the opposite effect was observed. Stimulation of the α-adrenergic receptors by phenylephrine (0.1 μg/ml) augmented the contracting effect of PGE$_1$; α-adrenergic blockade by phentolamine (0.1 μg/ml) had no effect on the reactivity of the gallbladder. The opposite motor effects of PGE$_1$ and isoproterenol on the isolated guinea pig bladder may depend on different effects of the two drugs on the cyclic AMP content of the organ. The data support the hypothesis that cholecystokinin and PGE have similar effects on the motor action of the musculature of the gallbladder.

5050 THE EFFECT OF PARIETAL CELL AND TRUNCAL VAGOTOMY ON GASTRIC AND DUODENAL CONTRACTILE ACTIVITY OF THE UNANESTHETIZED DOG. *(E.)*

Walker, G. D.; Stewart, J. J.; Bass, P. (Univ. Wisconsin Med. Ctr., Madison). *Ann. Surg.* 179(6):853-858, 1974.

The effect of parietal cell and truncal vagotomy on the motor function of the stomach and duodenum was studied in dogs in the interdigestive (fasted) and digestive (fed) states as well as under the influence of insulin (centrally acting), bethanechol, and histamine (smooth muscle acting). Motility index measurements were made with the use of strain gauge transducers sewn on to the serosal surface of the organ to be studied. Two distinct contractile patterns were present in the normal interdigestive state, whereby body and antral activity is associated with duodenal inhibition and duodenal activity is associated with diminished body and antral contractions. In animals with parietal cell vagotomy, this reciprocal inhibition was less prominent. Animals with a truncal vagotomy, however, possessed very little body or antral activity although the duodenum still contracted. The motility index measurements indicate that the basal state, as revealed by amplitude of contractions occurring during periods of low contractile activity between bursts, was unaffected by parietal cell or truncal vagotomy on either the antrum or duodenum. In the digestive state, parietal cell vagotomy resulted in continuous activity in the antrum but quiescent, short burst type activity in the duodenum. Truncal vagotomy resulted in a low continuous antral activity, with duodenal activity similar to that in parietal cell vagotomy. The response to insulin of animals not subjected to vagotomy was one of continuous body and antral activity with interrupted duodenal activity, a pattern similar to that observed during digestion in normal animals. Following parietal cell vagotomy, insulin caused a decreased body response, while following truncal vagotomy, insulin was without effect on the body and antrum. With either parietal cell or truncal vagotomy, insulin stimulated the duodenum. Bethanechol and histamine had no significant effects on antral response, regardless of the surgical condition, and bethanechol had no effect on duodenal response. However, histamine stimulated significantly the duodenum of animals with parietal cell vagotomy. It was concluded that parietal cell vagotomy had minimal disruptive effects on the antral-duodenal relationship while truncal vagotomy reduced antral contractile activity.

5051 GASTROINTESTINAL TRANSIT TIME IN OVARIAN CARCINOMA IRRADIATED WITH ^{60}CO. *(E.)*

Frankendal, B.; Junghagen, P. (Dept. Gynecol. Radiat. Ther., Umea Univ., Sweden). *Acta. Radiol.* [*Ther.*] *(Stockh.)* 13(2):129-140, 1974.

At least 4 weeks postoperatively, the effect of standarized abdominal ^{60}cobalt irradiation treatment on gastrointestinal transit time in 29 patients (31-75 yr) with ovarian carcinoma was determined by a standarized roentgen examination. Films of the abdomen were exposed every 1/2 hr with the patients prone after the medium had been swallowed, until it had begun to pass the ileocecal valve; patients were allowed to move about at will between exposures. Transit time was defined as the interval between the moment the patient swallowed the contrast medium and the moment it first appeared in the cecum. Conventional barium sulfate medium (200 ml) was used in 16 patients, while 13 received a physiologic contrast medium containing barium sulfate and nutritive substances: protein, fat, and carbohydrates, stabilized by trisodium citrate, and made up to 300 ml. Acceleration in the passage of the latter medium was demonstrated at 0-2000, 2000-4000, and 0-4000 rad (radiation absorbed dose). Only in the 6 patients in whom transit time was determined at 0-4000 rad and in whom the treatment series included a 15 day pause after 2000 rad was no acceleration evident. It is suggested that radiation-induced acceleration disappeared during the pause and returned when the irradiation was resumed. With the conventional medium, shortening of he time occurred at the dose difference of 0-4000 ad both after continuous treatment and after split-ourse treatment. However, no significant decrease n time could be recorded at dose differences of 0-2000 rad and 2000-4000 rad; in addition, no change was seen in association with the pause.

5052 CHANGES IN THE FREQUENCY OF THE SLOW WAVE FROM THE SMALL INTESTINE UPON PARTIAL AND FULL TRANSVERSE SECTION.

(E.) Kortezova, N. I. (Inst. Physiol., Bulgarian Acad. Sci., Sofia). *Dokl. Bolgar. Acad. Nauk.* 26(7):977-980, 1973.

Dogs were operated on to produce: transverse section of the longitudinal muscular layer of the small intestine with preservation of the circular layer and the mucosa; section of the circular muscular layer with preservation of the longitudinal layer and the mucosa; or section of both muscular layers with the mucosa and subsequent end-to-end joining. All of these surgical procedures led to a sharp drop in the frequency of the slow wave under the incision, with the frequency in the segment above remaining the same. In all cases, the drop in frequency took place gradually with the onset of arhythmia in the underlying segment. The gradient of the frequency of the slow wave was also disturbed. After the first month postoperatively, separate groups of slow waves with regular rhythm appeared periodically. The disruptions were most transient following section of the circular muscular layer only. In all groups, the difference between the frequencies of the slow wave above and below the section decreased with time. The longitudinal muscular and its appurtenant portion of the intramural nervous system, as well as the plexus submucosus, play an essential part in the propagation of the slow potential and in the adoption of this rhythm by the distally situated segment.

5053 FURTHER OBSERVATIONS ON THE SPASMOGENIC ACTIVITY OF CAERULEIN ON THE RAT PLYORUS.

(E.) Bertaccini, G.; Impicciatore, M.; De Caro, G.; Chiavarini, M.; Burani, A. (Inst. Pharmacol., Univ. Parma, Italy). *Pharmacol. Res. Commun.* 6(1):23-34, 1974.

The contracting activity of cerulein on the gastroduodenal junction of anesthetized female Wistar rats was compared with that of different peptidic and nonpeptidic spasmogenic compounds (phyllocerulein, cerulein heptapeptide, cerulein pentapeptide, cerulein tripeptide, cerulein dipeptide, cholecystokinin, bombesin, eledoisin, physalemin, bradykinin, acetylcholine, histamine, 5-hydroxytryptamine, morphine, barium chloride). Cerulein in doses as low as 2-5 ng/kg exerted a potent spasmogenic effect on the pyloric sphincter, while 160 ng/kg caused a complete block of duodenal effluent which lasted 20 min. With the exception of phyllocerulein and bombesin, which were as active as cerulein, all of the substances tested were much less active than the decapeptide. Several drugs (methysergide, lysergide, isoprenaline, orciprenaline, *N*-butylsopolammonium bromide, metoxamine, propranolol, xylamide, propenzolate, phemamide, diphemanil methyl sulfate thiemonium iodide, papaverine, 1-methyl-3-benzyloxyquinulidinium, dichloroisoproterenol, octopamine, dibenamine, prosympal, dihydroergotamine, atropine, mepyramine, pheniramine, epinephrine, and norepinephrine) were tested for their ability to antagonize the spasmogenic activity of cerulein on the pyloric sphincter. Of these drugs, only the sympathomimetic agents were able, at relatively low dose levels, to inhibit the effect of cerulein. The spasmogenic activity of cerulein may be 'physiologically' related to the stimulation of biliary and pancreatic secretion elicited by the peptide.

5054 ACTIONS OF CHOLECYSTOKININ AND SECRETIN ON THE MOTOR ACTIVITY OF THE SMALL INTESTINE IN MAN.

(E.) Gutierrez, J. G.; Chey, W. Y.; Dinoso, V. P. (Issac Gordon Ctr. Digest. Dis., Rochester, N. Y.). *Gastroenterology* 67(1):35-41, 1974.

The effects of cholecystokinin (CCK) and secretin on motor activity of the small intestine were studied by an intraluminal pressure recording technique in 24 healthy subjects (13 women and 11 men, aged 20-60 yr). CCK (1, 2, and 4 U/kg/hr i.v.) stimulated nonrhythmic type I waves in the duodenum and jejunum. Type III activity also tended to be increased, but this was not statistically significant. In contrast, secretin (0.5, 1, and 2 U/kg/hr i.v.) inhibited nonrhythmic type I and III waves. Interactions between the 2 hormones showed that CCK-stimulated upper intestinal motility was inhibited by secretin, and that secretin-inhibited motility was stimulated by CCK. The stimulatory effect of CCK on small bowel motor activity in man is in agreement with the previously reported stimulation of canine duodenal and jejunal motor activity by the C-terminal octapeptide of CCK. This study indicates that both CCK and secretin participate in the autoregulation of small bowel motility in man.

5055 EFFECT OF INSULIN ON THE REACTIVITY OF ISOLATED GUINEA PIG GALLBLADDER.

(Pol.) Stasiewicz, J.; Szalaj, W.; Gabryelewicz, A.; Kinalska, I. (Acad. Med., Bialystok, Poland). *Przegl. Lek.* 30(2):247-249, 1973.

SECRETION AND METABOLISM

5070 ADAPTIVE RESPONSES IN HEPATIC AND INTESTINAL CHOLESTEROGENESIS FOLLOWING ILEAL RESECTION IN THE RAT. *(E.)* Weis, H. J.; Dietschy, J. M. (Med. Clin., Johannes Gutenberg Univ., Mainz, Germany). *Eur. J. Clin. Invest.* 4(1):33-41, 1974.

Groups of Sprague-Dawley rats were prepared with a complete resection of either the jejunum or the ileum to study rates of cholesterol synthesis in the liver and small bowel. Fecal excretion of neutral and acidic sterols were measured 52 to 54 days after surgery and compared with similar measurements made in control animals that had had transection and reanastomosis of the intestine. Following resection of the ileum, the fecal excretion of neutral sterols (cholesterol + coprostanol) increased from 2.18 to 4.12 mg/day/100 g. In addition, the taurocholic acid pool decreased from 11.3 to 3.9 mg/100 mg, and the half-life for this bile acid declined from 2.8 to 0.4 days; hence, the metabolic production rate of taurocholic acid increased from 2.71 to 6.70 mg/day/100 mg. Coincidental with this accentuated turnover of both neutral and acidic sterols, the rate of *de novo* synthesis of cholesterol in the liver and small bowel (as judged by the rate of incorporation of 2-^{14}C-acetate into digitonin precipitable sterols) increased to a nearly identical degree in the animals with ileal resection. This was accomplished in the liver solely by an increase in the rate of synthesis per unit weight of tissue while in the intestine there was an increase in the weight of the jejunum as well as an increase in the rate of cholesterol synthesis per unit weight of tissue. The experimental group with jejunectomy did not differ significantly from control animals in rates of hepatic and intestinal cholesterol synthesis or in rates of eutral and acidic sterol excretion. These findings ndicate that following resection of the ileum in he rat there is increased endogenous synthesis of holesterol that fully compensates for the augmented xcretion of sterols which follows this operation so hat the circulating serum cholesterol pool remains ssentially unchanged.

SECRETION AND METABOLISM

Stomach

5078 SOME PRELIMINARY FINDINGS ON THE EFFECT OF ACUPUNCTURE ON SECRETION AND ACID-INDUCED ULCERS IN THE RAT STOMACH. *(E.)* Dai, S.; Low, D. D.; Ng, C. K.; Ogle, C. W. (Fac. Med., Univ. Hong Kong). *Am. J. Chinese Med.* 2(2):181-191, 1974.

Preliminary findings are reported on the effect of acupuncture on gastric secretion and motility and on the incidence of acid-induced ulcers in female Wistar rats with pyloric occlusion. Two different sets of acupuncture loci were used: (1) those commonly used for the treatment of gastric ailments (acupuncture loci) and (2) those used for other purposes (acupuncture control loci). Acupuncture, when compared with its own acupuncture controls, did not significantly affect either the rate of gastric secretion or total acid output. Ether anesthesia tended to lower the rate of gastric secretion and total acid output. The incidence of rumenal ulceration, induced by the accumulation of gastric secretion over a period of 5 hours after pyloric occlusion, was 94% in the untreated controls. Acupuncture significantly reduced the incidence of ulceration in those receiving acupuncture between 30 minutes and 3 hours after pyloric occlusion. Atropine sulfate (0.8 mg/kg) and acupuncture significantly reduced the number of amberlite pellets passed out of the stomach when compared with controls. Although gastric secretion appears to be unaffected by acupuncture, there is a relationship between the lowering of gastric motility and a decrease in the incidence of rumenal ulceration. The mechanism by which stimulation at the various acupuncture loci is effective remains to be defined.

5079 GASTRIC SECRETION IN RELATION TO PARATHYROID DYSFUNCTION IN RATS WITH CHRONIC GASTRIC FISTULAE. *(E.)* Arnthorsson, G.; Ohrn, P. G.; Segerstrom, A. (Univ, Hosp., Uppsala, Sweden). *Uppsala J. Med.* 78:48-54, 1973.

Male Sprague-Dawley rats with chronic gastric fistulas were parathyroidectomized or treated with excess parathyroid hormone (80 USP-U/100 g/day s.c.). In the parathyroidectomized rats, no changes were seen in the gastric secretion of hydrogen ions, chloride, or mucus, as represented by total and free sialic acid. However, in the animals treated with excess parathyroid hormone, the gastric secretory volume and hydrogen ion concentration decreased, while the gastric mucus secretion increased slightly; the chloride concentration remained unchanged. The results indicate that the reduced gastric acidity seen in experimental hyperparathyroidism is consistent with an increased reflux of acid into the mucosa, or alternatively, a reduced secretion of hydrogen ions. In this way, altered parathyroid function might influence the physiology of the stomach, so that in the hyperparathyroid state it would be more susceptible to ulceration. The accelerated emptying of the stomach might protect the stomach but increase the acid load in the duodenum and the risk of duodenal ulceration.

5080 EFFECTS OF ETHANOL ON GASTRIC MUCOSAL ADENOSINE 3',5' MONOPHOSPHATE (cAMP).

(E.) Tague, L. L.; Shanbour, L. L. (Univ. Texas Med. Sch., Houston). *Life Sci.* 14(6):1065-1073, 1974.

The effects of ethanol on adenylate cyclase activity *in vitro* and *in vivo*, phosphodiesterase activity *in vitro*, and the cyclic adenosine monophosphate content *in vivo* were investigated in the gastric mucosa of Sprague-Dawley rats. NaF-stimulated adenylate cyclase activity was inhibited *in vitro* and *in vivo* by 20% ethanol. Consistent results could not be obtained without NaF since basal adenylate cyclase activity was so low (0.05 ± 0.10 pmol/min/mg protein). The phosphodiesterase activity was about 350 times greater than basal adenylate cyclase activity. Exposure to 2.0-20.0% ethanol significantly inhibited phosphodiesterase activity *in vitro*. Ethanol (5-20%) produced no measurable changes in the content of cyclic adenosine monophosphate in the gastric mucosa *in vivo*. These results suggest that cyclic adenosine monophosphate probably does not play a role in pathological responses of the gastric mucosa to ethanol although both adenylate cyclase and phosphodiesterase are inhibited by ethanol.

5081 THE GASTRIC ANTISECRETORY ACTIVITY OF PYRIDYL-2-THIOACETAMIDE (CMN 131). *(E.)*

Pascaud, X. B.; Errard, D. J.; Blouin, M. M. (Science Union, Co., Suresnes, France). *Am. J. Dig. Dis.* 19(6):503-515, 1974.

A thiocarboxamide derivative, pyridyl-2-thioacetamide (CMN 131), was investigated for its gastric antisecretory properties in male Sprague-Dawley rats and in mongrel dogs. CMN 131 activity following intraduodenal administration was determined in 4 hr pylorus-ligated rats and in gastric fistula rats under basal and carbachol-stimulated (18 μg/kg/hr s.c.) conditions. ED_{50} of acid output inhibition was 1.46 (0.92-2.31) mg/kg with intraduodenal administration and 3.85 (2.65-5.59) mg/kg s.c. The inhibition was further confirmed in Heidenhain-pouch dogs whose gastric secretion was stimulated by i.v. pentagastrin (3.20 μg/kg/hr) and i.v. histamine (160 μg/kg/hr). Under all conditions, CMN 131 in doses ranging from 1 to 10 mg/kg, whatever the administrative route, possessed a long-acting antisecretory property characterized first, by its significant depressing effect upon acid concentrations during basal secretion in rats and also with maximal pentagastrin and histamine stimulation in dogs; and second, by an equal inhibitory potency on gastric secretion stimulated by histamine and pentagastrin in dogs. With maximal continuous stimulation, a stable inhibition period of more than 3 hr resulted from a single i.v. dose of CMN 131 to dogs. Activity of CMN 131 followed the 2-component hypothesis in regard to Na^+ secretion, i.e. a very significant correlation occurred between H^+ and Na^+ whatever the inhibitory level. In addition, CMN 131 had an important inhibitory effect on both the concentration and output of pepsin. These results indicate that the compound CMN 131 may act at the parietal cell level by a mechanism which needs further research to elucidate the exact pattern of H^+ gastric production.

5082 DOSE-RESPONSE RELATION BETWEEN SYNTHETIC SALMON CALCITONIN AND GASTRIC ACID OUTPUT WITH AND WITHOUT STIMULATION BY PENTAGASTRIN.

(E.) Henrichs, H. R.; Heissmeyer, H. H.; Karg, R.; Petersen, K. G.; Petrin, A.; Kerp, L. (Med. Clin., Univ. Freiburg, Germany). *Acta Endocrinol. (suppl.)* 75(184):170, 1974.

Gastric acid output, concentration of total and ionized calcium and concentration of immunoreactive calcitonin were determined in male subjects during 4 to 6 hours. After evaluation of basic acid output, stimulated acid output was measured during constant infusion of 0.6 μg/kg/hr pentagastrin. While continuing the pentagastrin infusion, synthetic salmon calcitonin was given i.v. for about 2.5 hours. One group of 3 healthy subjects received stepwise increasing doses of 0.015, 0.031, 0.065, 0.124 μg/kg/45 min. of calcitonin. A second group of 5 was given 0.065 μg/kg/hr and a third group of 3 subjects was given 0.108 μg/kg/hr calcitonin infusions. In all 3 groups, gastric acid output increased during pentagastrin administration and decreased during calcitonin administration. There was no apparent relationship between reduced gastric acid output and a decrease of total and ionized serum calcium levels. It was concluded that calcitonin inhibits gastric acid output by direct action on gastric parietal cells without interference of serum calcium.

5083 COMPARISON OF GASTRIC AND PANCREATIC INHIBITORY PROPERTIES OF METIAMIDE AND ATROPINE.

(E.) Konturek, S. J.; Tasler, J.; Obtulowicz, W.; Cieszkowski, M. (Med. Acad., Krakow, Poland). *Biol. Gastroenterol. (Paris)* 7(1):29-35, 1974.

In dogs with chronic gastric and pancreatic fistulas, the effects of metiamide, (N-methyl-N'-(2[(5-methyl-imidazol-4yl)methio]ethyl)thiourea), a potent histamine-receptor antagonist, were compared with the effects induced by atropine on both gastric and pancreatic responses to various stimuli. Metiamide (2.9 mg/kg/hr) caused a strong inhibition of gastric acid secretion in response to histamine (80 μg/kg/hr, pentagastrin (2 μg/kg/hr), urecholine (100 μg/kg/hr), and a peptone meal. Atropine (100 μg/kg/hr) did not affect histamine-induced secretion but did inhibit responses to all other stimuli. Pancreatic secretion of bicarbonate and protein induced by secretin (1 U/kg/hr), duodenal acidification (4.0 mEq/hr), or cerulein (250 ng/kg/hr) was inhibited by atropine but virtually not affected by metiamide. This study shows that, in comparison with atropine, metiamide has a wider spectrum of inhibitory action on gastric secretion and shows a more favorable ratio of desired effects in depressing gastric secretion to undesirable side effects, such as inhibition of pancreatic secretion.

5084 EFFECT OF GLUCAGON AND PANCREATIC SECRETION ON PEPTIC ULCER FORMATION IN CATS. *(E.)* Konturek, S. J.; Demitrescu, T.; Radecki, T.; Thor, P.; Pucher, A. (Med. Acad., Krakow, Poland). *Am. J. Dig. Dis.* 19(6):557-564, 1974.

Gastric and pancreatic secretion as well as peptic ulcer formation were investigated in conscious cats with gastric and pancreatic fistulas. Intravenous infusion of glucagon (25 µg/kg/hr) caused a dose-related inhibition of gastric secretion induced by pentagastrin (0.5, 1, 2, 4, 8, or 16 µg/kg/hr) and by pH 5.0 peptone meal, but did not block secretion induced by histamine (160 µg/kg/hr). The dose response curves to pentagastrin alone and in combination with glucagon, as seen by Michaelis-Menten analysis, were typical of noncompetitive inhibition. Glucagon also inhibited pancreatic bicarbonate and protein outputs evoked by exogenous secretin (1.0 U/kg/hr), duodenal acidification, and pH 5.0 peptone meal. The formation of pentagastrin-induced (8 µg/kg/hr for 36 hr) peptic ulcers was prevented by glucagon, but ulcers induced by histamine were not so prevented. The blocking action of glucagon against pentagastrin-induced peptic ulcers, attributed mainly to its inhibitory effect on gastric acid and pepsin secretion, deserves meticulous attention because of possible usefulness for therapeutic purposes.

5085 THE ROLE OF GLUCOCORTICOIDS IN REGULATING SECRETION OF MUCOID COMPOUNDS BY THE STOMACH IN DOGS. *(Rus.)* Mozheiko, L. A. (Grodno Med. Inst., USSR). *Farmakol. Toksikol.* 36(5):560-561, 1973.

Histochemical studies were made of the sialomucin, sulfated mucin, and neutral mucopolysaccharide contents of the stomachs of 90 dogs and changes produced in them by feeding and administration of hydrocortisone. Secretion of all 3 types of mucins increased within 15 min after feeding, particularly in the surface epithelium and mucus cells of the pylorus. Newly synthesized secretion appeared in the apical part of the cells, while glycogen accumulated in the basal part. By 2 hr after feeding the acid mucopolysaccharide content had decreased in the chief cells, perhaps due to secretion of pepsinogen, and the processes of synthesis and secretion had attained equilibrium. After a single injection of hydrocortisone (5 mg/kg) little change occurred in the content of polysaccharide components. Sulfated mucins decreased slightly in the pit epithelium, while glycogen decreased in the rugal epithelium. Secretion from the glandular epithelium predominated over synthesis in the secretory granules when three 5 mg/kg doses of hydrocortisone were administered in 1 day. Injection of 5 or 50 mg/kg hydrocortisone for 10 days markedly suppressed synthesis of sulfated and sialomucins and, to a somewhat lesser extent, that of neutral mucopolysaccharides. No glycogen was observed in the surface epithelium, but the glycogen content of parietal cells increased, and massive deposits were observed in chief and accessory cells in the curvature. The number of fat cells decreased in the lamina propria and submucosa of the stomach. These findings suggest that hydrocortisone may cause disturbances in the mechanism of gastric secretion by either indirect or direct means.

5086 RECEPTORS INVOLVED IN THE ACTION OF 5-HT AND TRYPTAMINE ON THE ISOLATED RAT STOMACH FUNDUS PREPARATION. *(E.)* Frankhuijzen, A. L.; Bonta, I. L. (Med. Fac., Erasmus Univ., Rotterdam, Netherlands). *Eur. J. Pharmacol.* 26(2):220-230, 1974.

The participation of alpha-adrenoceptors in drug-induced effects on isolated stomach fundus preparation from male albino Wistar rats was investigated. The drugs (0.1 ml/5 ml organ bath) used were acetylcholine iodine; serotonin creatinine sulfate; tryptamine hydrochloride; methysergide hydrogen maleinate; mianserin hydrochloride; cyproheptadine hydrochloride; and piperoxan. Recognized anti-serotonin agents were also studied to determine whether the same type of receptors are involved in the responses of rat fundus to serotonin and tryptamine. Methysergide was a very active, slowly reversible inhibitor of the serotonin-induced fundic contractions, reaching a maximum after 2 hr preincubation. Piperoxan (an α-adrenolytic agent) was a competitive antagonist of serotonin, able to prevent or reduce the anti-serotonin activity of mianserin, cyproheptadine, and methysergide, indicating a common site of action. All antagonists affected the serotonin induced contractions more than those induced by tryptamine. It is suggested that the effect of serotonin on the fundus is a result of interaction of serotonin with one type of receptor, probably the classical D-tryptamine receptor, although the possibility of a stimulant α-adrenoceptor is not excluded. The response to tryptamine is the result of an interaction by tryptamine with two different types of receptors: one type is identical to that mediating the response to serotonin, while the other type is more resistant to inhibition by methysergide, piperoxan, cyproheptadine, or mianserin and may be identical with the phenoxybenzamine-resistant receptor.

5087 PROSTAGLANDIN E_2 AND THE STIMULATION OF RAT GASTRIC ACID SECRETION BY DIBUTYRYL CYCLIC 3',5'-AMP. *(E.)* Main, I. H. M.; Whittle, B. J. R. (Sch. Pharm., Univ. London, England). *Eur. J. Pharmacol.* 26(2):204-211, 1974.

In female Wistar rats, i.v. injection of dibutyryl cyclic 3',5'-AMP (4-20 mg/kg) caused a dose-dependent increase in gastric acid secretion during stimulation by pentagastrin (0.2 µg/kg/min), histamine (25 µg/kg/min), or carbachol (0.1 µg/kg/min). This was accompanied by a rise in gastric mucosal blood flow.

During basal secretion, dibutyryl cyclic AMP caused only relatively slight stimulation, although this response was greatly enhanced by threshold doses of pentagastrin or histamine. This cyclic AMP did not stimulate acid secretion, but did increase mucosal blood flow and decreased blood pressure. Theophylline (20 mg/kg) had no consistent effect on acid secretion. Prostaglandin E_2 (2.0 μg/kg/min i.v. or 5 μg/ml perfused through the gastric lumen at 0.2 ml/min) reduced reduced basal acid secretion but did not inhibit the secretory response to dibutyryl cyclic AMP. The present observations add support to the hypothesis that cyclic AMP plays a role in gastric acid secretion. The failure of prostaglandin E_2 to inhibit dibutyryl cyclic AMP stimulation *in vivo* is further evidence that prostaglandins inhibit other secretogogues at a stage prior to cyclic AMP activation of the secretory process. However, these conclusions depend on the untested assumption that dibutyryl cyclic AMP has an identical mode of action to endogenous cyclic AMP.

5088 EXPERIMENTAL EVALUATION OF THE "GASTRIC BARRIER" IN CSF SHUNT INFECTIONS. *(E.)*

Selker, R. G.; Bahnson, D.; Norden, C. A.; Wolfson, S. K., Jr. (Univ. Pittsburgh Sch. Med., Pa.). *J. Surg. Res.* 16(5):541-545, 1974.

In vitro and *in vivo* experiments were conducted to determine the effect of gastric pH on organisms infecting cerebrospinal fluid shunts. Gastric pH levels were analyzed in 10 patients (2-9 yr) during fasting, natural sleep, anesthesia, as well as at various times up to 120 min after feeding. Milk and formula feedings had considerable buffering effect on the gastric pH fasting value, raising levels up to pH 4.78, 15 min after feeding, but dropping to pH 2.08, 120 min after feeding. *Staphylococcus albus* and *Pseudomonas aeroginosa* were used to study the *in vitro* effect of gastric pH on common shunt bacteria and on duration of exposure. With 15 min exposure, very few colonies survived in solutions of less than pH 3, but growth was uninhibited at pH over 4. This limited critical range was further narrowed to a pH lethal range between 3.5 and 3.8. Stumptailed macaques and baboons fed a standard diet and infused via tube with 1-50 million *Serratia* bacteria/ml showed no evidence of pigmented *Serratia* in daily stool cultures, thus indicating the impenetrability of the gastric pH barrier. In investigating the possible use of low pH fluids (well tolerated and readily available) to achieve the critical pH level, no growth occurred after 15 min of bacterial exposure to Coca Cola; similar results were obtained with ginger ale. Should successful implantation of drainage from infected cerebrospinal shunt systems into the stomach be accomplished in an infant or child, regurgitation and aspiration could prove detrimental with the infection spreading to involve the lungs. However, antibiotic therapy and an adequate cough reflex should be sufficient to minimize this effect as it does with normal gastric content in infants where vomiting is common.

5089 STEP-DOSE COMPARED TO SEPARATE-DOSE RESPONSE GASTRIC SECRETION WITH HISTAMINE AND PENTAGASTRIN IN DOGS - A KINETIC ANALYSIS. *(E.)*

Hirschowitz, B. I.; Hutchinson, G. (Dept. Med., Univ. Alabama, Birmingham). *Scand. J. Gastroenterol.* 9(2):207-217, 1974.

In 7 fistula dogs, gastric juice volume and H, Cl, Na, K, and pepsin secreted in response to graded doses of histamine in 8 separate single doses (2-125 μg/kg/hr) and in 7 incremental 45-min steps (2-150 μg/kg/hr) on the same day were compared with the responses to pentagastrin given in 7 single separate doses (0.1-6 μg/kg/hr) and in 6 incremental 45-min steps (0.1-5 μg/kg/hr). For separate-dose histamine, peak output occurred in the 4th to 8th sample after beginning the single dose infusion, with the longer delays occurring at the lower doses. In almost all the step doses, maximum output occurred in the 3rd 15-min period of each 45-min dose step. For pentagastrin, peak output was mostly in the 3rd and the 4th 15-min period of single dose infusion and in the 2nd of the three 15-min periods of each step dose. The calculated H+ maximum output (Vmax) was in the order separate-dose pentagastrin > separate-dose histamine > step-dose histamine > step-dose pentagastrin in the ratios 100:99:92:80. The Vmax for step-dose pentagastrin was significantly lower than the others, presumably due to fade with pentagastrin. Values for volume, Cl^-, Na^+, K^+, and pepsin were similarly and proportionately affected by a change in drug or in mode of drug administration. Km values (doses which stimulated output at 50% of Vmax rates) were in the order step-dose histamine > separate-dose histamine > separate-dose pentagastrin > step-dose pentagastrin, in a molar ratio of 100:50:0.7:0.35. Pepsin was stimulated by pentagastrin in a dose-dependent fashion; it was not stimulated by histamine. The shorter step-dose technique, with certain provisos and corrections, is appropriate for comparing and characterizing drugs acting on gastric secretion and for describing the stomach under study.

5090 GASTRIC HISTAMINE METABOLISM AFTER ACUTE PYLORIC LIGATION IN THE SHAY RAT. *(E.)*

McAlpin, C. D.; Moore, T. C.; Lemmi, C. A. E. (Univ. California Los Angeles-Harbor Gen. Hosp., Torrance). *Arch Surg* 109(1):65-67, 1974.

Acute pyloric ligation (Shay preparation) in male, inbred Lewis rats caused increases with peak elevations in both gastric histamine formation from histidine decarboxylase enzyme activity (12-fold) and total cellular histamine content (2-fold) of the stomachs 4 hr postligation. Return to essentially normal levels for both occurred 24 hr after ligation. This peak elevation period was also the approximate time of peak increases of gastric secretion in volume and acidity observed by others in the Shay rat. In the interval between 4 and 24 hr, gastric histidine decarboxylase activity remained somewhat elevated above normal levels while gastric histamine concentration was slightly depressed. Subcellular gastric concentrations of histamine were increased in the mitochondrial and supernatant fraction, decreased in the microsomal fraction, and unchanged in the nuclear fraction. These findings indicate that increased gastric histidine decarboxylase activity and histamine content are related temporally to increases in gastric secretion in volume and acidity which appear before peptic ulceration occurs. The increases in the mitochondrial and supernatant subcellular concentrations of histamine in the early post ligation period suggest that these subcellular components may be of importance in the changes observed following acute pyloric ligation in the rat.

SECRETION AND METABOLISM

Pancreas

5111 EXOCRINE PANCREATIC SECRETION AND OUTPUT OF BILE IN HUMANS UNDER CONDITIONS OF HYPOGLYCEMIA AND ADMINISTRATION OF ATROPINE. *(E.)* Wolfert, W.; Hartmann, W.; Hotz, J. (Univ. Ctr. Internal Med., Pediatr., Ulm, Germany). *Digestion* 10(1):9-16, 1974.

Possible neural, as compared to hormonal, regulation of exocrine pancreatic secretion, bile output, and gastric HCl secretion was investigated in 18 healthy volunteers (11 male, 7 female) with constant duodenal infusion of secretin (1 clinical U/kg), to all subjects, after an initial i.v. injection of 2 clinical U/kg 30 minutes previously. Subsequent measurements of pancreatic secretion as to volume, enzymes (trypsin and amylase), and bicarbonate; of bile output; and of gastric HCl secretion, were made under the following conditions: i.v. insulin (0.25 U/kg) to one group to produce hypoglycemia; the same insulin administration plus 10% glucose infused for the remainder of the test to a 2nd group; and atropine (1 mg) both i.v. and s.c. followed by i.v. insulin (0.25 U/kg) to a 3rd group. Hypoglycemia produced increased output and concentration of trypsin and amylase, and greater levels of bile output and HCl secretion. Atropine did not block any insulin effects except the HCl secretion increase due to hypoglycemia. Simultaneous infusion of glucose counteracted the effects of insulin. Because some expected atropine effects were not realized here, it is postulated that a higher dose of atropine (not possible in man) would be necessary. However, other vagolytic drugs with lesser side effects in humans might be more effective on the pancreas and on bile output in insulin hypoglycemia, especially under the assumption that the latter is a strong vagal stimulus. Atropine inhibition of vagally stimulated pancreatic secretion has been demonstrated in animal experiments.

5112 THE EFFECT OF DIPHENYLHYDANTOIN ON EXOCRINE PANCREATIC FUNCTION. *(Ger.)* Heidbreder, E.; Heidland, A. (Med. Clin., Univ. Wurzburg, Germany). *Dtsch. Med. Wochenschr.* 99(18):958-960, 1974.

Exocrine secretion was studied in the perfused isolated pancreas of fasted, pentabarbital-anesthetized male and female cats during intraarterial infusion of secretin (0.2 U/min) or after single intraarterial injections of cholecystokinin-pancreozymin (0.125 U) or acetylcholine (1 μg). A single intraarterial injection of diphenylhydantoin (10-75 mg) decreased the output of pancreatic juice. This decrease lasted only a short time with smaller doses of the drug but persisted or was only partially reversible after larger doses. Simultaneously, significant increases occurred in the total outputs of lipase, amylase, and total protein. No clear-cut relation was found to exist between enzyme secretion and the dose of diphenylhydantoin. Infusion of atropine (1.1×10^{-5}M) failed to inhibit enzyme liberation. Diphenylhydantoin had no effect on secretion of Na^+, K^+, and Cl^-, but it did cause a slight decrease in total Ca^{++} and Mg^{++}, at least after administration of smaller doses. It is suggested that stimulation of enzyme secretion by diphenylhydantoin may be mediated by nonspecific effects stimulating acinar cells such as changes in membrane permeability with an increased influx of cations or acinar cell damage.

5113 ACETYLCHOLINE CAUSES A NET DECREASE IN PHOSPHATIDYLINOSITOL AND A NET INCREASE IN PHOSPHATIDIC ACID IN MOUSE PANCREAS. *(E.)* Hokin-Neaverson, M. (Dept. Psychiatry, Physiol. Chem., Univ. Wisconsin, Milwaukee). *Biochem. Biophys. Res. Commun.* 58(3):763-768, 1974.

In order to see whether there were any net changes in the levels of phospholipids in response to acetylcholine in the pancreas, *in vitro* incubation of mouse pancreas with acetylcholine (10^{-5}M and 10^{-7}M) was performed. The 10^{-5}M concentration led to a net decrease (1.31 to 0.93 mols/g fresh tissue) of phosphatidylinositol levels and to a net increase (0.45 to 0.82 μmols/g fresh tissue) of phosphatidic acid levels. There were no significant changes in the levels of phosphatidylinositol and of phosphatidic acid with 10^{-7}M acetylcholine. (In all vessels to which acetylcholine was added, eserine sulfate, 10^{-4}M, was also added in order to inhibit acetylcholine-esterase activity.) When atropine was added to acetylcholine-stimulated tissue, the above changes were reversed: the level of phosphatidic acid fell and the level of phosphatidylinositol rose. The levels of other phosphatides which were measured (phosphatidylcholine, phosphatidylethanolamine, phosphatidylserine, sphingomyelin, and lysophosphatidylcholine) did not change significantly.

5114 ENZYMATIC ACTIVITY AND DIVALENT CATION CONTENT OF PANCREATIC JUICE. *(E.)* Sullivan, J. F.; Burch, R. E.; Magee, D. F. (Creighton Univ., Omaha, Nebr.). *Am. J. Physiol.* 226(6):1420-1423, 1974.

Some of the various pancreatic enzymes have been shown to be metalloenzymes, and this study was undertaken to evaluate the relationship of calcium, magnesium, and zinc content of pancreatic juice with volume, protein content, protease, and amylase activity in pigs in the basal state and following stimulation. Secretin was given i.v. throughout each experiment at a rate of 0.25 U/min in 2 ml of saline. Vagal stimulation, 10-20 min, increased amylase activity to a greater extent than total protein or protease activity. There was a 16-fold increase of zinc output, 4-fold increase in magnesium, and nearly a 3-fold mean increase in calcium, upon vagal stimulation. Cholecystokinin, administered i.v. (10 U), resulted in a much steeper relationship between zinc and protease, and between zinc and total protein than did vagal stimulation or gastrin pentapeptide (i.v., 10 μg). In general, cholecystokinin stimulation produced a 29% increase in total volume, together with increased outputs of zinc, calcium, protein, protease, and amylase, but not magnesium. Administration of gastrin pentapeptide yielded increased production of zinc, calcium, and magnesium. These divalent cations, which appear to be bound to protein, correlate with the amylase and protease activities measured in pancreatic juice. Other calculated correlation coefficients and plotted regression lines are analyzed and discussed.

5115 ACETYLCHOLINE INCREASES THE LEVEL OF DIGLYCERIDE IN MOUSE PANCREAS. *(E.)* Banschbach, M. W.; Geison, R. L.; Hokin-Neaverson, M. (Dept. Pediatr., Psychiatry, Physiol. Chem., Univ. Wisconsin, Milwaukee). *Biochem. Biophys. Res. Commun.* 58(3):714-718, 1974.

The effect of acetylcholine on the pool size of diglycerides in mouse pancreas *in vitro* was investigated to test the hypothesis that diglycerides are a product of phosphatidylinositol and phosphatidic acid breakdown induced by acetylcholine. The quantitative analysis of diglycerides was made possible by use of a rapid, sensitive radiometric procedure. Incubation of Swiss-Webster mouse pancreas with 10^{-5} or 10^{-4} M acetylcholine plus 10^{-4} physostigmine, added to inhibit acetylcholine-esterase activity, significantly increased tissue diglyceride levels. Diglyceride rose from 0.5 μM/g fresh tissue in unstimulated pancreas to 1.2 μM with 10^{-5} acetylcholine and to 3.6 μM with 10^{-4} M acetylcholine. The linear increase in diglyceride level with time at 10^{-4} M acetylcholine was blocked and reversed by 10^{-5} M atropine. When atropine was added, the diglyceride level fell to the control, unstimulated value. The increase in diglyceride level was greater than could be accounted for by hydrolysis of phosphatidylinositol or phosphatidic acid. Thus, acetylcholine-induced changes in the level of pancreas diglycerides are not directly linked to changes in phospholipid metabolism. Rather, they may represent a separate effect with potential for changing properties of pancreatic membrane elements.

5116 PLASMA ENZYME AND ISOENZYME CHANGES DURING PERFUSION OF THE ISOLATED PIG LIVER. *(E.)* Buttery, J. E.; Parbhoo, S. P.; Baron, D. N. (Roy. Free Hosp., London, England). *Clin. Sci. Mol. Med.* 46(1):105-112, 1974.

Changes in the perfusate activities of aspartate transaminase, lactate dehydrogenase, its 'LD-5' component, sorbitol dehydrogenase, ornithine carbamoyltransferase, and the isoenzyme patterns of lactate dehydrogenase and aspartate transaminase were investigated during the perfusion of 11 pig livers with human blood. The aspartate transaminase values were sensitive indicators of liver damage provided the degree of hemolysis was small. Appearance on electrophoresis of the mitochondrial isoenzyme of aspartate transaminase indicated severe liver damage. Sorbitol dehydrogenase activity was also a sensitive index of liver cell damage, and one in which hemolysis did not interfere. The total lactate dehydrogenase activity was an unreliable indicator of liver cell damage in that it largely reflected the degree of hemolysis rather than liver cell damage. However, the isoenzyme pattern of lactate dehydrogenase on electrophoresis distinguished liver cell damage from hemolysis. The chemical determination of 'LD-5' was not a sensitive index of pig liver damage, as this fraction is found only in low concentration in pig liver. Ornithine carbamoyltransferase was a poor marker of liver cell damage.

5117 EFFECTS OF NUTRITIONAL STATE AND OF ADMINISTRATION OF GLUCOSE GLIBENCLAMIDE OR DIAZOXIDE ON THE STORAGE OF AMYLASE IN MOUSE PANCREAS. *(E.)* Danielsson, A. (Univ. Umea, Sweden). *Digestion* 10:150-161, 1974.

The relation between endocrine and exocrine pancreatic secretion was studied by measuring pancreatic amylase levels during starvation followed by refeeding and also effects of substances influencing insulin secretion. Starvation up to 48 hr induced a considerable fall in pancreatic amylase content of pancreas in female mice, which was readily restored by refeeding.. The enzyme changes were parallel to variations in serum glucose and insulin. After starvation the amylase content could be increased by i.p. glucose (7 g/kg) or the insulin secretagoue glibenclamide (4 mg/kg). The glucose-induced rise in amylase content was abolished by concomitant i.p. diazoxide (200 mg/kg), an inhibitor of glucose-induced insulin release. These findings suggest that insulin has a role in maintaining a high level of amylase in the exocrine pancreas. The parotid gland displayed a transient increase in amylase content during starvation, followed by a decrease to normal if starvation continued. No direct relation to variations in serum glucose and insulin was observed.

5118 AUGMENTED ACID AND GASTRIN RESPONSE TO MEALS AFTER PANCREATIC DUCT LIGATION. *(E.)*

Peterson, J. J.; Militello, J. M.; Go, V. L. W.; Wilson, S. D. (Med. Coll. Wisconsin, Milwaukee). *J. Surg. Res.* 16(4):353-359, 1974.

The role of gastrin in the hypersecretion induced by pancreatic duct ligation was studied in 8 mongrel dogs with denervated Heidenhain fundic pouches with Gregory cannulas. Pancreatic duct ligation resulted in significant 24-hr gastric hypersecretion from the denervated fundic pouches. Fasting serum gastrin concentrations after ligation were not significantly different from those in control period. Antrectomy reduced the 24 hr acid secretion to near control levels, and fasting serum gastrin was lowered. The acid response during the first 2 hr after a standard meal was markedly augmented in dogs with pancreatic duct ligation. Peak gastrin concentrations were significantly increased at 30 and 60 minutes after a standard meal in dogs with pancreatic duct ligation. The 2-hr integrated gastrin response to a meal was increased after ligation. Antrectomy abolished both the augmented acid and agumented gastrin response to a meal. It is concluded that an augmented gastrin response in pancreatic duct ligation animals results from the inadequate release of a fat-stimulated hormone from the duodenum and proximal small bowel that normally occurs during a meal and that this hormone acts in part to inhibit meal-stimulated gastrin release from the antrum.

Hepatobiliary Tract

5124 TOTAL BODY WASHOUT AND EX VIVO LIVER PERFUSION IN ACUTE HEPATIC FAILURE. A COMPARATIVE STUDY. *(E.)*

Wakabayashi, A.; Kubo, T.; Gilman, P.; Charney, K.; Connolly, J. E. (Dept. Surg., Univ. California, Irvine). *Arch. Surg.* 109(1):52-56, 1974.

The efficiency of *ex vivo* liver perfusion and total body washout to clear bilirubin in the treatment of acute hepatic failure was compared in jaundiced mongrel dogs. Six hour *ex vivo* liver perfusion was performed in 5 dogs by perfusing the portal vein of the *ex vivo* liver with blood from the recipient's artery. Hepatic venous blood from the *ex vivo* liver was returned to the recipient's vein by a pulsatile blood pump. Total body washout was performed in 6 dogs using hypothermic cardiopulmonary bypass. All animals tolerated both procedures well. With *ex vivo* liver perfusion, serum bilirubin levels fell from 4.93 to 0.86 mg/100 ml, a clearance rate of 78.38%. With total body washout, bilirubin levels fell from 6.74 to 0.54 mg/100 ml, a clearance rate of 91.62%, significantly higher than that of *ex vivo* liver perfusion. These results indicate that both ex vivo liver perfusion and total body washout are equally safe in the treatment of liver failure, but total body washout appears to be more efficient and rapid in clearing circulating toxic substances than does *ex vivo* liver perfusion.

5125 PROTECTION FROM BILIRUBIN NEPHROPATHY IN JAUNDICED GUNN RATS. *(E.)*

Odell, G. B.; Bolen, J. L.; Poland, R. L.; Seungdamrong, S.; Cukier, J. O. (Johns Hopkins Univ. Sch. Med., Baltimore, Md.). *Gastroenterology* 66(6):1218-1224, 1974.

Since bilirubin nephropathy in adult homozygous jaundiced Gunn rats (jj) is associated with abnormally high bilirubin concentrations accumulated in the renal papillae (not seen, however, up to weaning at about 21 days), this study was undertaken to observe the chronological development of the condition and also the possible prevention by lowering circulating bilirubin levels. The inclusion of agar, with its high binding affinity for bilirubin, 2% by weight in the diet of 17 (jj) rats resulted in greater fecal excretion of bile pigments as measured by bilirubin and urobilin. No influence of age was seen in the 6-15 month old animals examined. The concentrations of bilirubin in serum, adipose tissue, and renal medullae were less than in 13 (jj) littermates fed a standard diet. Comparison of renal clearance of free water in 5 month old animals showed that standard diet (jj) animals had significantly lower rates than heterozygous nonjaundiced rats (Jj), but rates for the agar diet (jj) animals did not significantly differ from the (Jj) rats. The preservation of normal renal clearance of free water by the agar diet (jj) rats was associated with a 20% reduction of bilirubin concentrations in the serum and adipose tissue. The mechanism by which agar increases bile pigment fecal excretion and lowers the circulating bilirubin concentration, and thereby decreases renal accumulation, is not certain; agar could bind bilirubin either derived from the biliary secretion or from that which enters the intestinal lumen by direct diffusion from the intestinal circulation. The results suggest that nephropathy of adult (jj) rats is secondary to the accumulation of bilirubin in the renal papillae rather than being a result of the genetically deficient medulla.

5126 THE PHYSICOCHEMICAL FACTOR REQUIRED FOR THE BILIARY EXCRETION OF ORGANIC CATIONS AND ANIONS.

(E.) Hirom, P. C.; Hughes, R. D.; Millburn, P. (St. Mary's Hosp. Med. Sch., London, England). *Biochem. Soc. Trans.* 2(2):327-330, 1974.

In this study, factors influencing biliary excretion of foreign organic compounds in the rat were investigated, including the necessary presence of a polar ionizable group (anion or cation) and a minimum molecular weight related to the crucial factor of lipid solubility. The partition ratios (P) of a structurally related series of 9 monoquaternary ammonium cation compounds and of 5 diquaternary ammonium cations, both sets ^{14}C-labeled, were measured between octan-1-ol and 0.1 M phosphate buffer, pH 7.4, a model system used for both biological lipid and aqueous phases. Sample (0.2 ml) of both the upper organic layer and the lower aqueous layer were then counted for ^{14}C. The log (P) values plotted against both molecular weights and % dose biliary excretion in rats showed high correlations, as did the extent of biliary excretion against the relative lipid solubility of the compounds, whether mono- or diquaternary, cation or anion. In general, those compounds with log (P) values of -2 or less were poorly excreted in the bile while those with values greater than -2 were more extensively excreted. These results suggest that the lipid solubility of polar organic cations and anions may be an important physicochemical factor in determining the extent to which they are eliminated in the bile. This implies that a certain balance between hydrophilic and hydrophobic properties (amphiphilicity) is required before a compound can cross liver cell membranes and enter bile.

5127 ACTIVATION OF ETHANOL UTILIZATION IN PERFUSED LIVER FROM NORMAL AND ETHANOL-PRETREATED RATS. THE EFFECT OF HYDROGEN PEROXIDE GENERATING SUBSTRATES.

(E.) Thurman, R. G.; McKenna, W. (Johnson Res. Fdn., Univ. Pennsylvania, Philadelphia). *Hoppe Seylers Z. Physiol. Chem.* 355 (3):336-340, 1974.

Hydrogen peroxide generating substrates such as glycolate (15 mM) or urate (0.5 mM) activated ethanol utilization by perfused rat livers from normal and ethanol-pretreated rats 2 to 3-fold above control rates in the presence of an inhibitor of alcohol dehydrogenase, 4-methylpyrazole. This stimulation of ethanol utilization was due to intraperoxisomal hydrogen peroxide generation, which led to the formation of catalase-H_2O_2. Concomitant with the elevated rate of ethanol utilization, the (lactate)/(pyruvate) ratio and (3-hydroxybutyrate)/(acetoacetate) ratio as indicators of the pyridine nucleotide redox state remained well oxidized. Thus, a combination of 4-methylpyrazole plus an H_2O_2-generating substrate could elevate the rate of ethanol metabolism, while simultaneously obviating the effects of an elevated pyridine nucleotide redox state.

5128 EVIDENCE FOR A ROLE OF THE MICROTUBULAR SYSTEM IN THE SECRETION OF NEWLY SYNTHESIZED ALBUMIN AND OTHER PROTEINS BY THE LIVER.

(E.) LeMarchand, Y.; Patzelt, C.; Assimacopoulos-Jeannet, F.; Loten, E. G.; Jeanrenaud, B. (Geneva Univ. Med. Sch., Switzerland). *J. Clin. Invest.* 53(6):1512-1517, 1974.

The interference with the integrity of liver microtubules by vinblastine, vincristine, or colchicine was studied in perfused livers (*in situ*) of 6-week-old male Swiss mice, and the secretion of albumin and protein was measured. After a lag period of 30 min, the release of newly synthesized proteins (with labeled amino acids) by control livers was linear for 90 min. When livers were perfused in the presence of vinblastine (100 μM), the secretion of labeled proteins was completely abolished, but there was no inhibition of total (i.e. hepatic plus perfusate) amino acid incorporation into proteins. Vinblastine also markedly affected lipid metabolism, i.e., triglyceride secretion was nearly abolished at a time when hepatic lipogenesis and triglyceride content were increased. In addition, this compound greatly inhibited ketone body production and somewhat decreased urea production. Newly synthesized protein secretion was noticeably inhibited (75%) by vincristine (2.5 μM). Cellular ATP content, glucose production, and fatty acid uptake were not modified by this drug. When livers were perfused with colchicine (10 μM), there was a 75% reduction in the appearance of labeled proteins in the perfusate. Total amino acid incorporation into proteins was not altered by either colchicine or vincristine, whereas hepatic amino acid incorporation into proteins was significantly higher in both vincristine and colchicine-treated livers than in control livers. More than 50% of the newly synthesized albumin was secreted into the perfusate of control livers. In the presence of vincristine or colchicine, the amount of newly synthesized albumin in the perfusate was drastically reduced, and the accumulation of labeled albumin within the liver was obvious although total albumin synthesis remained unchanged. Chromatographic separation of the various secreted proteins showed vincristine and colchicine decreased release of albumin, globulins, and small polypeptides to a similar extent. It is possible that variations in the hepatic microtubular system may play a more important role in the physiologic regulation (and perhaps also in the pathology) of albumin and globulin secretion than has previously been suspected.

5129 BILIARY EXCRETION OF PHENOL RED IN WISTAR AND GUNN RATS. *(E.)* Homan, E. R.; Guarino, A. M. (Lab. Toxicol., Natl. Cancer Inst., Bethesda, Md.). *Proc. Soc. Exp. Biol. Med.* 146(1):46-49, 1974.

Biliary excretion of phenol red and of phenol red glucuronide was studied in male Gunn and normal Wistar rats. Although phenol red is normally excreted by the kidneys, it may appear in rat bile as a free compound or as a glucuronide conjugate. For this investigation, both Gunn and Wistar rats had renal pedicle ligation. In Gunn rats, direct reacting bilirubin levels were twice those of Wistar rats while total bilirubin levels were approximately 15 times higher. The amount of free phenol red excreted in the bile was about the same in the 2 strains of rats, but Wistar rats excreted 32 to 35% of the phenol red as a glucuronide whereas only free phenol red was found in Gunn rat bile. Bile/plasma and bile/liver concentration ratios of free phenol red in Wistar rats were higher than those in Gunn animals. The phenol red exhibited a mild choleretic effect in both strains.

5130 ENHANCEMENT OF MICROSOMAL DRUG HYDROXYLATION AND GLUCURONIDATION IN RAT LIVER BY PHENOBARBITAL AND 3-METHYLCHOLANTHRENE IN COMBINATION. *(E.)* Vaino, H.; Aitio, A. (Dept. Physiol., Univ. Turku, Finland). *Acta Pharmacol. Toxicol.* 34:130-140, 1974.

Both 3-methylcholanthrene and phenobarbital increased the O-demethylation of *p*-nitroanisole in male Wistar rat liver microsomes (9-fold and 6-fold, resp.), whereas 3-methylcholanthrene alone was able to enhance the aryl hydrocarbon hydroxylase activity 13-fold. When the inducers were administered to rats in combination, the enhancement in O-demethylase activity of *p*-nitroanisole was greater and of aryl hydrocarbon hydroxylase was smaller than when administered singly. Both 3-methylcholanthrene and phenobarbital also enhanced the microsomal UDP glucuronyltransferase activity when measured after *in vitro* activation of the latent enzyme. The hepatic UDP glucuronyltransferase activity was increased about 2-fold after 3-methylcholanthrene pretreatment of rats as measured from the nonactivated microsomes. The pretreatment of rats with 3-methylcholanthrene and phenobarbital brought about no additional effect, when calculated on a microsomal protein basis. If calculated on 100 gram body weight basis, however, an additive effect was observed in UDP glucuronyltransferase activity due to the effects of the inducers on the liver weight/body weight ratio.

5131 EARLY CHANGES IN BILE COMPOSITION AND GALLSTONE FORMATION INDUCED BY A HIGH CHOLESTEROL DIET IN PRAIRIE DOGS. *(E.)* DenBesten, L.; Safaie-Shirazi, S.; Connor, W. E.; Bell, S. (Univ. Iowa Coll. Med., Iowa City). *Gastroenterology* 66(5):1036-1045, 1974.

Changes in the composition of hepatic and gallbladder bile during the early phases of gallstone formation were studied in adult male prairie dogs which were fed a cholesterol-free diet or 1.2% high cholesterol diet containing 41% of calories as egg yolk fat. Essential fatty acids constituted 2.2% of the total calories in the control diet and 3.28% in the lithogenic diet. Paired groups of animals fed the high and low cholesterol diets were killed 36 hr, 5 days, and 14 days after the diets were begun. After 36 hr, the serum cholesterol level was 427 mg/dl in animals fed the high cholesterol diet, and 143 mg/dl in the low cholesterol diet group. The liver cholesterol levels were 6.97 mg/g tissue in the cholesterol-free rats after 36 hr and 15.29 in the high cholesterol animals. After 5 days, the respective values were 8.40 and 16.78; after 14 days, 9.82 and 17.48. The bile cholesterol concentration was greater in cholesterol-fed animals (5.2 vs. 2.2, expressed as a percentage of total moles of cholesterol, phospholipid, and bile acid). Cholesterol-fed animals had a higher mole fraction of phospholipid (9.7 vs. 7.0) but the total bile acid fraction was less (85.0 vs. 90.8). Groups of animals killed at 5 and 14 days had further differences in the relative cholesterol concentrations in bile; concentrations of phospholipid and total bile acids also differed significantly from those measured in paired animals fed a low cholesterol diet. With the high cholesterol, egg yolk diet, the predominant bile acid in fresh gallbladder and hepatic bile shifted from cholic acid to chenodeoxycholic acid. Cholesterol crystals were found in the gallbladder bile of all high cholesterol-fed animals at 5 days; gallstones were present in 5 of 7 of these prairie dogs at 14 days. Dietary cholesterol overload in this animal model produced early supersaturation of cholesterol in bile, with subsequent cholesterol precipitation and gallstone formation.

5132 EFFECT OF BILE ACIDS ON CHOLESTEROL SYNTHESIS IN PERFUSED RAT LIVER. *(Ger.)* Barth, C.; Liersch, M.; Hackenschmidt, J.; Ullmann, J.; Decker, K. (Biochem. Inst., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1373-1375, 1972.

Experiments on perfused rat livers showed that cholic and taurocholic acids in the enterohepatic circulation do not cause short-term inhibition of cholesterol or fatty acid synthesis. Taurocholic acid (10 mg/100 g/hr) was infused for 1 hr into the portal vein of rats which had been fed a diet containing 2% cholestyramine for 7 days. Infusion was followed by two 40 min periods during which bile acid was discontinued, the last period corresponding to interruption of the enterohepatic circulation and serving as a control period. Measurements of 1-^{14}C-labeled acetate incorporation revealed that no change had occurred in the rate of hepatic cholesterol or fatty acid synthesis. Infusion of taurocholic acid for 3 had no effect on the synthesis rate or redox tatus of ketone bodies or on the activities of LDH, lutamate-oxaloacetate transaminase, or glutamate- yruvate transaminase in the perfusion medium. No oxic effect on mitochondrial function or on the iver cell membrane was observed. Within 40 min after iscontinuing 1 hr of taurocholate infusion, 95% of he bile acid administered had been excreted again in he bile. Since about 1/3 of the cholic acid in ortal vein blood is present in the nonconjugated orm, this experiment was repeated with free cholic cid (dose unspecified) which likewise had no effect n hepatic cholesterol or fatty acid synthesis. hese findings do not rule out the possibility that ile acids may inhibit hydroxymethylglutaryl-CoA eductase *in vivo*.

133 DEPLETION OF BRAIN NOREPINEPHRINE IN ACUTE HEPATIC COMA.

(E.) Dodsworth, J. M.; ames, J. H.; Cummings, M. C.; Fischer, J. E. (Dept. urg., Harvard Med. Sch., Boston, Mass.). *Surgery* 5(6):811-820, 1974.

he time course of accumulation of the neurotrans- itter norepinephrine and the false neurotransmitter ctopamine was measured in brains of female Sprague awley rats with acute hepatic coma induced by porta- aval anastomosis, followed, 48 hr later, by hepatic rtery ligation. Results were compared to those ob- ained on a variety of controls which had undergone epatic artery ligation, acute portacaval shunt, and ham operation. Brain octopamine levels did not iffer significantly between sham-operated animals nd normal unoperated animals. Following hepatic rtery ligation, some decrease in brain octopamine as seen, but an increase occurred 48 hr after acute hunt. However, if hepatic artery ligation was per- ormed on an already shunted animal, the brain octo- amine increased approximately 300 to 400% above levels seen in hepatic artery ligation alone. Heart ctopamine increased markedly after 6 hr of acute hepatic coma and then rose gradually until the animals were moribund. Brain norepinephrine did not differ significantly between normal rats, sham-operated animals, rats with hepatic artery ligation alone, and animals with acute portacaval shunt alone. When the rats became symptomatic at 6 hr, brain norepinephrine decreased, reaching a final depletion of approximately 50% in the moribund stage. In animals injected with ^{3}H-d,l-norepinephrine, no difference occurred in initial uptake or turnover whether expressed in terms of turnover or specific activity. In those injected with ^{3}H-l-norepinephrine, uptake was greater in the brains of animals in coma. The results suggest that synthesis of norepinephrine is decreased in acute hepatic coma, but much more research is required to determine whether this diminution is caused by displacement, decreased synthesis, or other factors.

5134 INSULIN AS THE PRIMARY FACTOR GOVERNING CHANGES IN MITOCHONDRIAL METABOLISM LEADING TO LIVER REGENERATION AND ATROPHY.

(E.) Ozawa, K.; Yamaoka, Y.; Nanbu, H.; Honjo, I. (Kyoto Univ. Fac. Med., Japan). *Am. J. Surg.* 127(6):669-675, 1974.

In this study investigating factors in hepatic regeneration, ligation of the left branch of the portal vein in male rabbits for 24 hr resulted in decreased phosphorylation rates of mitochondria of liver cells from the ligated lobe with glutamate substrate in the isolating medium, and a marked rate increase in mitochondria from cells of the unligated lobe. However, when 5 g liver slices from the ligated lobe were incubated in a medium containing crystalline insulin (13 μg/ml) for 10 minutes, the respiratory control ratio, state 3 respiration, P:O ratio, and phosphorylative activity of the mitochondria, depressed by portal deprivation, increased to greater levels with glutamate substrate than with succinate, nearly equalling those of mitochondria from the unligated lobe. A more marked enhancement was observed with NAD-linked substrates than with succinate, as seen in mitochondria from the unligated lobe. The addition of glucagon to the incubation mixture did not appreciably enhance the mitochondrial phosphorylative activity of liver slices from the ligated lobe. These findings suggest that insulin may play an important regulatory role in possibly activating some portal factor which may trigger enhanced oxidative phosphorylation of liver mitochondria, such an increase being requisite for later rise in nuclear DNA leading to greater liver regeneration.

5135 SITES OF COMPETITION IN THE SELECTIVE HEPATIC UPTAKE OF RIFAMYCIN-SV, FLAVASPIDIC ACID, BILIRUBIN AND BROMSULPHTHALEIN.

(E.) Kenwright, S.; Levi, A. J. (Clin. Res. Ctr., Harrow, England). *Gut* 15(3):220-226, 1974.

The effect of rifamycin-SV (3.6 μM/100 g) and flavaspidic acid (5 μM/100 g) on the hepatic uptake of BSP (6 μM/100 g) was measured *in vivo* in Sprague-Dawley rats and was compared with the ability of these drugs to displace BSP from ligandin and Z protein *in vitro*. The effect of rifamycin-SV on the distribution of bilirubin in the liver cell and its subfractions was also investigated *in vitro* in homozygous Gunn rats to determine whether this drug could selectively displace bilirubin from ligandin or Z protein. Both rifamycin-SV and flavaspidic acid impaired uptake of BSP *in vivo*, whether given 10, 30, or 60 min before BSP. In contrast to rifamycin-SV, which had little effect on the binding of BSP to ligandin and Z protein, flavaspidic acid, when present in only 1/10 of the molar concentration of BSP, displaced more than half of the BSP from Z protein. However, flavaspidic acid displaced BSP from ligandin only when the drug was added in a 10-fold molar excess. With low concentrations of flavaspidic acid, binding of BSP to ligandin increased slightly. Rifamycin-SV increased serum bilirubin concentrations over control levels and reduced bilirubin levels in total liver, supernatant, pellet, ligandin, and Z protein to about the same extent, while flavaspidic acid increased pellet bilirubin levels and displaced bilirubin primarily from Z protein. These findings suggest that flavaspidic acid primarily affects bilirubin uptake by competition for binding to Z protein, but that rifamycin-SV competes at an earlier step, perhaps at the plasma membrane level. Addition of rifamycin-SV to Gunn rat liver supernatant in concentrations similar to those found in the *in* *vivo* experiments and at more than twice the molar concentration of bilirubin, reduced bilirubin bound to the Z fraction to 80% of control values and slightly increased bilirubin binding to ligandin and the X fraction. Thus, rifamycin-SV causes gross impairment of BSP uptake *in vivo* but does not displace BSP from ligandin or Z protein *in vitro*. This suggests that the uptake defect is not likely to be due to competition for binding to these proteins.

5136 NEONATAL CHANGES IN THE CONCENTRATION OF RAT LIVER CYCLIC AMP AND OF SERUM GLUCOSE, FREE FATTY ACIDS, INSULIN, PANCREATIC, AND TOTAL GLUCAGON IN MAN AND IN THE RAT. *(E.)*

Blazquez, E.; Sugase, T.; Blazquez, M.; Foa, P. P. (Sinai Hosp. Detroit, Mich.). *J. Lab. Clin. Med.* 83(6):957-967, 1974.

Changes occurring in serum insulin and glucagon were investigated during the first 24 hr of life in human babies and spontaneously delivered Wistar rats and from days 19-22 of gestation in fetal Wistar rats. Changes in serum glucose and free fatty acid levels were studied and, in the rat, the activity of cyclic AMP in the liver. In both rats and humans, prenatal anabolic processes are reversed during the transition from placental to oral nutrition, partly due to inhibition of insulin and stimulation of glucagon secretion. In human neonates, serum glucose and insulin decreased 1 hr after birth and remained low during the first day. Serum free fatty acids and serum pancreatic glucagon levels increased 3 hr after delivery and remained elevated for the rest of the day. Serum glucagon-like immunoreactivity represented mostly serum pancreatic glucagon until 24 hr after birth. By that time the babies had received their first feeding. On day 21 of gestation, serum glucose levels were equal in fetal rats and in their mothers. On day 22, fetal glucose levels were higher, but decreases occurred immediately after birth. Serum pancreatic glucagon remained the same during the last few days of gestation in fetal rats, but increased significantly 15 min after birth; reached a maximum 3 hr after birth, and remained elevated during the first day. No changes occurred in fetal serum free fatty acids during gestation, but levels increased on days 19-21 of gestation and decreased on day 22. Hepatic cyclic AMP increased in fetal rats during days 19-22 of gestation. Serum nonpancreatic glucagon immunoreactivity decreased after birth but increased with the onset of nursing.

5137 SINUSOIDAL STENOSIS AS THE CAUSE OF PORTAL HYPERTENSION IN CHOLINE DEFICIENT DIET INDUCED FATTY CIRRHOSIS OF THE RAT LIVER. *(E.)*

Wada, K.; Fujimoto, K.; Fujikawa, Y.; Shibayama, Y.; Mitsui, H.; Nakata, K. (Osaka Med. Coll., Japan). *Acta Pathol. Jap.* 24(2):207-217, 1974.

Results demonstrated by Donryu strain male rats fed a choline deficient diet were used to investigate a possible anatomical lesion responsible for portal hypertension. Portal vein pressures, hemodynamic analysis of isolated perfused livers, diameter measurement of intrahepatic vascular trees, histological, and histometrical examinations were used in this investigation. The mean portal vein pressure was elevated from 132 to 175 mm H_2O in fatty liver, to 179 in fatty liver with fibrosis, and to 218 in fatty cirrhosis of liver. The hepatic blood flow of the isolated perfused rat liver (pressure 135 mm H_2O) decreased from the normal level, 3.0 ml/g/min to 1.2 ml/g/min in fatty liver, to 0.4 in fatty liver with fibrosis and to 0.7 in fatty cirrhosis of liver. There was no abnormality in the pre- and post-sinusoid vessel, but the sinoidal space was diminished due to enlargement of the hepatic cells. There was a significant correlation between portal hypertension and sinusoidal space decrease. Connective tissue proliferation did not affect increase in hepatic vascular resistance. These findings demonstrate that the reduction of sinusoidal space was the anatomical lesion related to the development of portal hypertension in choline-deficient-diet induced fatty liver as well as fatty cirrhosis of the liver (sinusoidal hypertension)

5138 THE EFFECTS OF VARYING IONIC COMPOSITION OF THE PERFUSATE ON LIVER MEMBRANE POTENTIAL, GLUCONEOGENESIS AND CYCLIC AMP RESPONSES. *(E.)*

Dambach, G.; Friedmann, N. (Univ. Pennsylvania Sch. Med., Philadelphia). *Biochim. Biophys. Acta* 332(3):374-386, 1974.

The hyperglycemic effects of glucagon and cyclic AMP on redistribution of cellular ions and on membrane hyperpolarization were investigated. Livers of male Sprague-Dawley rats was perfused *in situ* with Krebs-Ringer bicarbonate buffer. Glucagon or cyclic AMP administration resulted in an increased glucose production, hyperpolarization of the liver cells, and a large efflux of intracellular Na^+. Total substitution of perfusate Na^+ with either Li^+ or choline lowered the membrane potential and resulted in an inhibition of the cyclic AMP-stimulated Na^+ efflux, membrane hyperpolarization, and glucose production, but did not block the cyclic AMP-stimulated Ca^{2+} efflux. With partial replacement of Na^+ by either Li^+ or choline, the responses to the cyclic nucleotides were normal. Partial substitution of Na^+ by 100 mM K^+ caused a depolarization of the liver cells, and responses to cyclic AMP under this condition were greatly reduced. Substitution of the extracellular Cl^- with isethionate did not inhibit these effects of cyclic AMP. These data are consistent with studies indicating that a functional connection might exist between the hormone- or cyclic AMP-induced ion fluxes, cell membrane hyperpolarization, and the metabolic effects evoked by these agents.

5139 PLASMA AMINO ACIDS IN EXPERIMENTAL ACUTE HEPATIC FAILURE AND THEIR RELATIONSHIP TO BRAIN TRYPTOPHAN. *(E.)*

Buxton, B. H.; Steward, D. A.; Murray-Lyon, I. M.; Curzon, G.; Williams, R. (Kings Coll. Hosp., London, England). *Clin. Sci. Mol. Med.* 46(4):559-562, 1974.

Eight large white pigs were fasted overnight and subjected to acute devascularization of the liver by portacaval anastomosis, followed by hepatic artery ligation. Blood samples were taken from the carotid artery at 2 hr intervals and the concentrations of 15 plasma amino acids were determined. After devascularization, the mean glycine, alanine, and methionine values increased significantly. Smaller rises in the concentrations of most of the other 12 amino acids measured were not statistically significant. The levels of tyrosine and phenylalanine in the cerebrospinal fluid also increased significantly following devascularization, while the concentration of arginine decreased. Altered plasma concentrations of 5 neutral amino acids (tyrosine, phenylalanine, leucine, isoleucine, valine) which compete with tryptophan for transport into the brain had no apparent influence on the brain tryptophan concentrations.

5140 EFFECT OF PROSTAGLANDIN E_1 ON HEPATIC CYCLIC AMP ACTIVITY, CARBOHYDRATE AND LIPID METABOLISM. *(E.)* Levine, R. A. (Upstate Med. Ctr., Syracuse, N.Y.). *Prostaglandins* 6(6):509-521, 1974.

Prostaglandin E_1 (PGE_1) failed to stimulate rat liver cyclic AMP (cAMP), induce hyperglycemia, glycogenolysis or lipolysis or prevent epinephrine-induced hyperglycemia in isolated perfused rat liver, even though other known glycogenolytic agents (glucagon and epinephrine) activated cAMP in this same system. The data do not support a physiologic role for PGE_1 on hepatic glycogenolysis or lipolysis. Although the effects of PGE_1 on gluconeogenesis, lipogenesis, ureogenesis or amino acid transport in isolated perfused liver were not investigated, if PGE_1 is subsequently found to influence these metabolic parameters, such alterations would probably occur independent of a change in cAMP activity.

5191 BIOTRANSFORMATION OF LITHOCHOLIC ACID AND ITS 3α-SULFATE DURING A SINGLE HEPATIC PASSAGE IN HEALTHY MAN. *(E.)* Cowen, A. E.; Korman, M. G.; Hofmann, A. F.; Cass, O. W. (Mayo Clin., Rochester, Minn.). *Gastroenterology* 66(4):678, 1974.

5192 EFFECT OF MAGNESIUM DEFICIENCY ON HEPATIC PROTEIN METABOLISM AND REGENERATION OF THE LIVER. *(E.)* Chen, S.; Flink, E. B. (Dept. Med., West Virginia Univ., Morgantown). *Gastroenterology* 66(4):674, 1974.

5193 COMBINED EFFECTS OF ALCOHOL AND PROTEIN DEPRIVATION ON METHIONINE METABOLISM IN RAT LIVER. *(E.)* Cello, J. P.; Finkelstein, J. D. (VA Hosp., Washington, D.C.). *Gastroenterology* 66(4):672, 1974.

5194 PRECIPITATION OF BILE SALTS BY CHLORPROMAZINE (CPZ); THE PROTECTIVE EFFECT OF LECITHIN (LEC). *(E.)* Carey, M. C.; Hirom, P. C.; Small, D. M. (Boston Univ. Sch. Med., Mass.). *Gastroenterology* 66(4):671, 1974.

5195 EFFECT OF FREQUENCY OF FEEDING UPON HUMAN BILIARY LIPID OUTPUT. *(E.)* Butt, J.; Hanson, K. (Univ. Missouri Med. Ctr., Columbia). *Gastroenterology* 66(4):670, 1974.

5196 CHOLIC ACID (CA) BINDING TO LIVER PLASMA MEMBRANE FRACTIONS (LPM). *(E.)* Accatino, L.; Simon, F. R. (Univ. Colorado Med. Ctr., Denver). *Gastroenterology* 66(4):657, 1974.

5197 THE ORIGIN OF LIVER LYSOSOMES, LIPID DEGRADATION IN HEPATOCYTES, AND A POSSIBLE MODEL OF CHOLESTEROL ESTER STORAGE DISEASES. *(E.)* Nehemiah, J. L. (Albert Einstein Coll. Med., Bronx, N.Y.). *Gastroenterology* 66(4):656, 1974.

5198 IMMUNITY TO Fasciola hepatica IN THE RAT: SUCCESSFUL TRANSFER OF IMMUNITY BY LYMPHOID CELLS AND BY SERUM. *(E.)* Armour, J.; Dargie, J. D. (Univ. Glasgow Vet. Sch., Scotland). *Exp. Parasitol.* 35(3):381-388, 1974.

5199 CHOLESTEROL OXIDATION BY RAT LIVER PREPARATIONS: EFFECT OF AGE. *(E.)* Story, J. A.; Kritchevsky, D. (Wistar Inst. Anatomy Biol., Philadelphia, Pa.). *Experientia* 30(3):242-243, 1974.

5200 ENZYMES OF GLYCEROL METABOLISM IN DEVELOPING RAT LIVER AND KIDNEY. *(E.)* Burch, H. B.; Lowry, O. H.; Delaney, L. M. (Washington Univ. Sch. Med., St. Louis, Mo.). *Enzyme* 17(3):168-178, 1974.

5201 LEUKOCYTIC PROTEASES IN GALLBLADDER PATHOLOGY. EXPERIMENTAL ACUTE CHOLECYSTITIS IN DOGS. *(E.)* Gonciarz, Z.; Trusz-Gluza, M.; Kusmierski, S.; Luciak, M. (Silesian Sch. Med., Katowice, Poland). *Digestion* 10(1):65-72, 1974.

5202 RELEASE OF PROTEASES FROM LEUKOCYTES BY DOG BILE IN VITRO. *(E.)* Gonciarz, Z.; Trusz-Gluza, M.; Kusmierski, S. (Silesian Sch. Med., Katowice, Poland). *Digestion* 10(1):61-64, 1974.

5203 CHANGES IN BILE FLOW IN THE RAT WITH SOME SOLVENTS AND DISPERSANTS USED AS PHARMACEUTICAL VEHICLES. *(It.)* Croce, G.; Ferrini, R. (Pharmacol. Lab., Simes Co., Milan, Italy). *Boll. Soc. Ital. Biol. Sper.* 49(11):653-659, 1973.

5204 SECRETION OF PHOSPHOLIPIDS AND CHOLESTEROL IN THE BILE OF RATS: ACTION OF PHENOBARBITONE. *(E.)* Gerolami, A.; Crotte, C.; Mule, A.; Domingo, N.; Durbec, J. P. (Res. Unit Digestive Dis., INSERM, Marseille, France). *Biomedicine* 20:160-168, 1974.

5205 LIPID METABOLISM OF RAT LIVER ISOLATED AND PERFUSED IN HYPOXIA. *(E.)* Soler-Argilaga, C.; Infante, R.; Polonovski, J. (St. Antoine Fac. Med., Paris, France). *Biomedicine* 20(1):154-159, 197

5206 THE INFLUENCE OF DIETHYLENETRIAMINEPENTAACETATE ON THE SYNTHESIS OF DNA, RNA AND PROTEINS IN THE REGENERATING RAT LIVER. *(E.)* Gabard, B. (Inst. Radiation Biol., Nuclear Res. Ctr., Karlsruhe, Germany). *Biochem. Pharmacol.* 23(4):901-909, 1974.

5207 THE INFLUENCE OF DL-A COMPATIBILITY ON THE SURVIVAL OF HEPATIC ALLOGRAFTS IN UNMODIFIED MONGREL DOGS. *(E.)* Ranson, J. H. C.; Rapaport, F. T.; Ferrebee, J. W.; Cannon, F. D.; Adams, P. X.; Localio, S. A. (New York Univ. Med. Ctr., N.Y.). *Ann. Surg.* 179(6):846-852, 1974.

5208 THE EFFECT OF GLUCAGON ON HEPATOSPLANCHNIC HEMODYNAMICS, FUNCTIONAL CAPACITY, AND METABOLISM OF THE LIVER IN CATS. *(E.)* Krarup, N.; Larsen, J. A. (Inst. Physiol., Univ. Aarhus, Denmark). *Acta Physiol. Scand.* 91(1):42-52, 1974.

5209 BINDING OF CADMIUM AND MERCURY IN THE RAT BILE: STUDIES USING GEL FILTRATION. *(E.)* Havrdova, J.; Cikrt, M.; Tichy, M. (Ctr. Ind. Hyg. Occupational Dis., Prague, Czechoslovakia). *Acta Pharmacol. Toxicol. (Kbh.)* 34(4):246-253, 1974.

5210 EFFECTS OF PHENFORMIN AND PHENFORMIN-ETHANOL SYNERGISM ON THE PERFUSED RAT LIVER. *(E.)* Olsen, C.; Krarup, N. (Inst. Physiol., Univ. Aarhus, Denmark). *Acta Pharmacol. Toxicol. (Kbh.)* 34(3):232-240, 1974.

5211 IMMEDIATE EFFECT (IN 3 TO 6 HOURS) OF A SINGLE DOSE OF (+)-CATECHOL ON BIOCHEMICAL

ISORDERS INDUCED IN THE LIVER OF THE ALBINO RAT. *r.)* Gajdos, A.; Gajdos-Torok, M.; Horn, R. (Biochem. es. Lab., Univ. Paris, France). *C. R. Soc. Biol. aris)* 167(11):1561-1564, 1973.

212 THE AFFINITY OF UDP-GLUCURONYLTRANSFERASE FOR CHLORAMPHENICOL. *(Ger.)* Linhart, P. ed. Clin., Univ. Heidelberg, Germany). *Verh. Dtsch. es. Inn. Med.* 79:936-938, 1973.

213 EFFECT OF A PORTACAVAL SHUNT ON THE ACTIVITY OF CYTOPLASMIC, MITOCHONDRIAL, AND MICROSO-AL ENZYMES IN NORMAL AND CIRRHOTIC RAT LIVER. *(Ger.)* ode, J. C.; Bode, C.; Zelder, O.; Middeler, A. (Med. lin., Univ. Marburg, Germany). *Verh. Dtsch. Ges. nn. Med.* 79:919-922, 1973.

214 THE EFFECT OF ETHANOL ON GLYCOGENOLYSIS AND GLUCONEOGENESIS IN THE HUMAN LIVER. *Ger.)* Dietze, G.; Wicklmayr, M.; Grunst, J.; Hepp, . D.; Braun, S.; Mehnert, H. (Schwabing Hosp., unich, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79: 11-914, 1973.

215 RELATIONS BETWEEN THE ACTIVITY OF THE DRUG-METABOLIZING ENZYME SYSTEM IN THE LIVER ND THE COURSE IN EXPERIMENTAL HEPATIC COMA. *(Ger.)* rachtel, D.; Thiel, H.; Zilly, W.; Richter, E. Med. Clin., Univ. Wurzburg, Germany). *Verh. Dtsch. es. Inn. Med.* 79:917-919, 1973.

216 BIOSYNTHESIS OF PROTEINS WHICH APPEAR IN RAT SERUM DURING LIVER REGENERATION. *(Ukr.)* olishchuk, A. S.; Danko, I. M.; Korotkoruchko, V. .; Bohdan, I. P. (O. V. Palladin Inst. Biochem., iev, USSR). *Ukr. Biokhim. Zh.* 45(5):559-560, 1973.

217 EXPERIMENTAL HEPATITIS INDUCED WITH D-GALACTOSAMINE. *(Fr.)* Keppler, D. (Fac. ed., Univ. Freiburg/Breisgau, Germany). *Ann. astroenterol. Hepatol. (Paris)* 9(3):211-221, 1973.

5218 COMPARATIVE STUDY OF VIRAL HEPATITIS SYMPTOMS IN ANIMALS INFECTED BY DIFFERENT METHODS. *(Rus.)* Priz, N. N. (Kiev Sci. Res. Inst. Epidemiol., Microbiol., Parasitol., USSR). *Vopr. Virusol.* (6):696-700, 1974.

5219 LIBERATION OF NEWLY SYNTHESIZED RNA FROM ISOLATED NUCLEI OF NORMAL AND REGENERATING LIVER. *(Rus.)* Rozet, E. G.; Teterev, N. I.; Panchenko, L. F.; Shuppe, N. G. (N. I. Pirogov 2nd Moscow Med. Inst., USSR). *Dokl. Akad. Nauk SSSR* 216(5):1188-1191, 1974.

5220 CHANGES IN ENZYME ACTIVITY AND METABOLITES (ATP, LACTATE) IN LIVER TISSUE BEFORE AND AFTER PRESERVATION. *(Ger.)* Wolff, H.; Walther, J.; Strassburger, P. (Surg. Clin., Karl Marx Univ., Leipzig, Germany). *Z. Exp. Chir. (Jena)* 6(3):150-155, 1973.

5221 RELATION BETWEEN THE ACTIVITIES OF GLUTATHIONE PEROXIDASE AND CATALASE IN HEPATIC HYPERPLASIA INDUCED WITH PHENOBARBITAL. *(Rus.)* Gerasimov, A. M.; Panchenko, L. F.; Koen, Ia. M.; Antonenkov, V. D. (N. I. Pirogov 2nd Moscow Med. Inst., USSR). *Dokl. Akad. Nauk SSSR* 216(5):1175-1177, 1974.

5222 EFFECT OF ETHANOL ON PURINE CATABOLISM IN THE HUMAN LIVER. *(Ger.)* Grunst, J.; Dietze, G.; Wicklmayr, M.; Mehnert, H.; Hepp, K. D.; Eisenburg, J. (Schwabing Hosp., Munich, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:914-917, 1973.

5223 ACTIVITY OF MONOAMINE OXIDASE IN VARIOUS TYPES OF HEPATOMAS DURING MALIGNANT TRANSFORMATION AND IN THE LIVERS OF RATS WITH TUMORS. *(Rus.)* Arzamastsev, V.P. (Orenburg Med. Inst., USSR). *Vopr. Med. Khim.* 19(3):282-286, 1973.

5224 ROLE OF GLUCOSE AND FRUCTOSE IN THE EFFECT OF HORMONES ON HEPATIC TRANSAMINASE ACTIVITY. *(Rus.)* Polikarpova, L. I. (Inst. Exp. Med., Leningrad, USSR). *Vopr. Med. Khim.* 19(3):299-301, 1973.

5225 REPLICATION OF NUCLEAR DNA IN REGENERATING RAT LIVER AND ZAJDELA ASCITES HEPATOMA. *(Rus.)* Komar, V. E.; Nikitina, Z. S.; Shutko, A. N.; Il'in, L. A. (Central Sci. Res. Inst. Roentgenol. Radiol., Leningrad, USSR). *Biokhimiia* 39(2):327-332, 1974.

5226 PRIMARY AND SECONDARY BIOCHEMICAL RESPONSE OF THE LIVER TO GALACTOSAMINE HEPATITIS AFTER ADMINISTRATION OF D-GALACTOSAMINE. *(Ger.)* Reutter, W.; Bauer, C.; Bachmann, W.; Lesch, R. (Biochem. Inst., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:927-930, 1973.

5227 RELATION BETWEEN PLASMA PHOSPHOLIPID COMPOSITION AND LIVER MICROSOMES IN EXPERIMENTAL CHOLESTASIS AND HEPATITIS. *(Ger.)* Gallenkamp, H.; Brachtel, D.; Richter, E. (Med. Clin., Univ. Wurzburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 79:930-933, 1973.

5228 INFLUENCE OF D-GALACTOSAMINE HYDROCHLORIDE ON MICROSOMAL PHOSPHOLIPID-, PROTEIN-, AND CYTOCHROME P_{450}-CONTENT IN GUINEA PIG LIVER. *(E.)* Gallenkamp, H.; Brachtel, D.; Richter, E. (Med. Clin., Univ. Wurzburg, Germany). *Acta Hepatogastroenterol.* 21(2):101-105, 1974.

5229 STUDIES IN LIVER CIRCULATION, LIGATIONS OF LIVER ARTERIES OR GALL DUCTS OF GUINEA PIGS.

(E.) Haller, C. V.; Lade, R. (Dept. Surg., Univ. Frankfurt/Main, Germany). *Acta Hepatogastroenterol.* 21(2):131-133, 1974.

5230 EFFECT OF RETINOL ON LIVER LIPID METABOLISM OF RATS. *(E.)* Misra, U. K. (Vallabhbhai Patel Chest Inst., Univ. Delhi, India). *Agr. Biol. Chem.* 38(2):247-252, 1974.

5231 RELEASE BY ETHANOL OF VITAMINS INTO RAT LIVER PERFUSATES. *(E.)* Sorrell, M. F.; Baker, H.; Barak, A. J.; Frank, O. (Univ. Nebraska Med. Ctr., Omaha). *Am. J. Clin. Nutr.* 27(7):743-745, 1974.

5232 LIVER CELL DIFFERENTIATION IN A CHEMICALLY DEFINED MEDIUM. MORPHOLOGIC AND ENZYMATIC COMPARISONS OF IN UTERO RAT LIVER AND LIVER RUDIMENT GROWN IN ORGAN CULTURE. *(E.)* Parsa, I. (Downstate Med. Ctr., State Univ. New York, Brooklyn). *Am. J. Pathol.* 76(1):107-122, 1974.

5233 PATHOMORPHOLOGIC AND HISTOCHEMICAL CHANGES IN THE LIVER DURING HEMODILUTION. *(E.)* Biernat, S.; Kulig, A.; Lepert, R.; Orlowski, T. (Military Med. Acad., Lodz, Poland). *Am. J. Surg.* 128(1):24-30, 1974.

5234 EFFECT OF VITAMIN B-12 DEPRIVATION ON THE RATES OF SYNTHESIS AND DEGRADATION OF RAT LIVER FATTY ACID SYNTHETASE. *(E.)* Frenkel, E. P.; Kitchens, R. L.; Johnston, J. M.; Frenkel, R. (Univ. Texas Southwestern Med. Sch., Dallas). *Arch. Biochem. Biophys.* 162(2):607-613, 1974.

5235 LOCATION OF A VERY ACTIVE BICARBONATE-DEPENDENT ATPase IN THE OUTER MEMBRANE OF RAT AND FROG LIVER MITOCHONDRIA. *(E.)* Grisolia, S.; Mendelson, J. (Kansas Univ. Med. Ctr., Kansas City). *Biochem. Biophys. Res. Commun.* 58(4):968-973, 1974.

5236 EFFECTS OF BICARBONATE ON INTERCOMPARTMENTAL REDUCING-EQUIVALENT TRANSLOCATION IN ISOLATED PARENCHYMAL CELLS FROM RAT LIVER. *(E.)* Berry, M. N.; Werner, H. V.; Kun, E. (Children's Hosp. Med. Ctr., Oakland, Calif.). *Biochem. J.* 140(3):355-361, 1974.

5237 HEPATIC DRUG HYDROXYLATION AND LIPID PEROXIDATION IN RIBOFLAVIN-DEFICIENT RATS. *(E.)* Patel, J. M.; Galdhar, N. R.; Pawar, S. S. (Div. Biochem., Marathwada Univ., Aurangabad, India). *Biochem. J.* 140(3):363-368, 1974.

5238 THE CONCENTRATION AND CONTROL OF CYTOPLASMIC FREE INORGANIC PYROPHOSPHATE IN RAT LIVER IN VIVO. *(E.)* Guynn, R. W.; Veloso, D.; Lawson, J. W. R.; Veech, R. L. (Natl. Inst. Mental Health, Washington, D. C.). *Biochem. J.* 140(3):369-375, 1974.

5239 INHIBITION BY LOCAL ANAESTHETICS OF ADENINE NUCLEOTIDE TRANSLOCATION IN RAT LIVER MITOCHONDRIA. *(E.)* Spencer, T. L.; Bygrave, F. L. (Fac. Sci., Australian Natl. Univ., Canberra). *Biochem. J.* 140(3):413-422, 1974.

5240 STUDIES ON THE LIPID COMPOSITION OF THE RAT LIVER ENDOPLASMIC RETICULUM AFTER INDUCTION WITH PHENOBARBITONE AND 20-METHYLCHOLANTHREN *(E.)* Davison, S. C.; Wills, E. D. (St. Bartholomews Hosp., London, England). *Biochem. J.* 140(3):461-468, 1974.

5241 DIURNAL RHYTHMS OF HEPATIC CARBOHYDRATE METABOLISM DURING DEVELOPMENT OF THE RAT. *(E.)* Walker, P. R.; Bonney, R. J.; Potter, V. R. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison). *Biochem. J.* 140(3):523-529, 1974.

5242 COMPARTMENTATION OF FREE AMINO ACIDS FOR PROTEIN SYNTHESIS IN RAT LIVER. *(E.)* Airhart, J.; Vidrich, A.; Khairallah, E. A. (Dept. Biochem. Biophys., Univ. Connecticut, Storrs). *Biochem J.* 140(3):539-548, 1974.

5243 AMINO ACID LEVELS IN LIVER AND PLASMA OF THE RAT DURING INHIBITION OF TRANSAMINATION. *(E.)* Gressner, A. M. (Inst. Biochem., Univ. Heidelberg Germany). *Biochem. Med.* 10(3):199-207, 1974.

5244 THE CHEMICAL FORM OF THE METHYLMERCURY COMPLEX IN THE BILE OF THE RAT. *(E.)* Ohsawa, M.; Magos, L. (Med. Res. Council Labs., Surrey, England). *Biochem. Pharmacol.* 23(13):1903-1905, 1974.

5245 ENERGY-DEPENDENT ACCUMULATION OF IRON BY ISOLATED RAT LIVER MITOCHONDRIA. III. SUBMITOCHONDRIAL LOCALIZATION OF THE IRON ACCUMULATED. *(E.)* Romslo, I.; Flatmark, T. (Dept. Biochem., Univ. Bergen, Norway). *Biochim. Biophys. Acta* 347(2):160-167, 1974.

5246 POSTNATAL DEVELOPMENT OF HEPATIC DRUG-METABOLIZING ENZYMES IN THE GUNN RAT. *(E.)* Yeary, R. A.; Gerken, D.; Davis, D. R. (Dept. Vet. Physiol. Pharmacol., Ohio State Univ., Columbus). *Biol. Neonate* 23(5/6):371-380, 1973.

5247 STUDIES ON THE CONVERSION OF MEVALONATE INTO BILE ACIDS AND BILE ALCOHOLS IN TOAD AND THE STEREOSPECIFIC HYDROXYLATION AT CARBON ATOM 26 DURING BILE ALCOHOL BIOGENESIS. *(E.)* Kuramoto, T.; Itakura, S.; Hoshita, T. (Hiroshima Univ. Sch. Med., Japan). *J. Biochem. (Tokyo)* 75(4):853-859, 1974.

5248 HORMONE-INDUCED CHANGES IN LIVER DNA SYNTHESIS: EFFECTS OF GLUCOCORTICOIDS AND GROWTH HORMONE ON LIVER GROWTH AND DNA POLYMERASE ACTIVITY.

(E.) Henderson, I. C.; Loeb, J. N. (Columbia Coll. Phys. Surg., New York). *Endocrinology* 94(6):1637-1643, 1974.

5249 THE SPECIFICITY OF THE RAT-LIVER CHOLESTEROL 7α-HYDROXYLASE. *(E.)* Brown, M. J. G.; Boyd, G. S. (Univ. Edinburgh Med. Sch., Scotland). *Eur. J. Biochem.* 44(1):37-47, 1974.

5250 MODE OF DEGRADATION OF RIBOSOMES IN REGENERATING RAT LIVER IN VIVO. *(E.)* Tsurugi, K.; Morita, T.; Ogata, K. (Niigata Univ. Sch. Med., Japan). *Eur. J. Biochem.* 45(1):119-126, 1974.

5251 RATE OF GLUCONEOGENESIS AND INTRACELLULAR CONCENTRATIONS OF INTERMEDIATES IN ISOLATED RAT HEPATOCYTES. *(E.)* Gimpel, J. A.; Zimmerman, U. J. P. (Johnson Res. Fdn, Univ. Pennsylvania, Philadelphia). *Fed. Proc.* 33(5) Pt. II:1559, 1974.

5252 PHENOBARBITAL (PB)-vs. 3-METHYLCHOLANTHRENE (3-MC)-INDUCED HEPATIC MICROSOMAL P-450. INDUCTION COURSE, BIOPHYSICAL-CHEMICAL INTERACTIONS AND PHOTOCHEMICAL ACTION SPECTRA. *(E.)* Copper, D. Y.; Schleyer, H.; Thomas, J. H.; Vars, H.; Rosenthal, O. (Harrison Dept. Surg. Res., Univ. Pennsylvania, Philadelphia). *Fed. Proc.* 33(5) Pt. II:1386, 1974

5253 KINETICS OF GLUCOSE UPTAKE BY PERFUSED RAT LIVERS AND ISOLATED RAT HEPATOCYTES: EVIDENCE FOR THE INVOLVEMENT OF SYNTHETIC ACTIVITIES OF MULTIFUNCTIONAL GLUCOSE-6-PHOSPHATASE. *(E.)* Alvares, F. L.; Gunderson, H. M.; Nordlie, R. C. (Univ. North Dakota, Med. Sch., Grand Forks). *Fed. Proc.* 33(5) Pt. II:1559, 1974.

5254 THE REGULATION OF KETONE BODY FORMATION IN PERFUSED GUINEA PIG LIVER. *(E.)* Ogata, K.; Hanson, R. W.; Weinhouse, S. (Temple Univ. Med. Sch., Philadelphia, Pa.). *Fed. Proc.* 33(5) Pt. II: 1559, 1974.

5255 STUDIES ON MOUSE LIVER URATE OXIDASE. III. FINE LOCALICATION OF URATE OXIDASE IN LIVER CELLS REVEALED BY MEANS OF ULTRACRYOTOMY-IMMUNOFERRITIN METHOD. *(E.)* Yokota, S.; Nagata, T. (Shinshu Univ. Sch. Med., Matsumoto, Japan). *Histochemistry* 39(3): 243-250, 1974.

5256 IN VIVO RATE OF TRANSLATION BY RIBOSOMES OF NORMAL AND REGENERATING LIVER. *(E.)* Scornik, O. A. (Dartmouth Med. Sch., Hanover, N.H.). *J. Biol. Chem.* 249(12):3876-3883, 1974.

5257 ENDOGENOUS PHOSPHOLIPIDS OF SWINE LIVER: EFFECTS OF FAT DEPRIVATION ON MOLECULAR SPECIES OF PHOSPHATIDYLCHOLINE AND PHOSPHATIDYLETHANOLAMINE. *(E.)* Shaw, J. M.; Bottino, N. R. (Dept. Biochem., Texas A&M Univ., College Station, Tex.). *J. Lipid Res.* 15(4):317-325, 1974.

5258 CORRELATION OF DOSE RATE AND BIOLOGICAL EFFECT IN RAT LIVER CELLS RESULTING FROM X-RAY, ^{113m}In, AND ^{198}Au IRRADIATION. *(E.)* Witcofski, R. L.; Pizzarello, D. J.; Smith, E. M.; Everhart, H.; Gnau, T. R. (Bowman Gray Sch. Med., Winston Salem, N.C.). *J. Nucl. Med.* 15(4):241-245, 1974.

5259 A COMPARISON OF THE EFFECTS OF DIETARY PROTEIN AND LIPID DEPRIVATION ON LIPID COMPOSITON OF LIVER MEMBRANES IN RATS. *(E.)* Gerson, T. (Dept. Sci. Ind. Res., Palmerston North, New Zealand). *J. Nutr.* 104(6):701-709, 1974.

5260 EFFECT OF DIETARY FATS AND FATTY ACIDS ON THE LIVER LIPID ACCUMULATION INDUCED BY FEEDING A PROTEIN-REPLETION DIET CONTAINING FRUCTOSE TO PROTEIN-DEPLETED RATS. *(E.)* Aoyama, Y.; Yoshida, A.; Ashida, K. (Dept. Agr. Chem., Nagoya Univ., Japan). *J. Nutr.* 104(6):741-746, 1974.

5261 DIFFERENTIAL EFFECT OF GLUTEN AND CASEIN DIETS ON RAT LIVER HMP SHUNT DEHYDROGENASES. *(E.)* Carrozza, G.; Livrea, G.; Manasseri, L.; Muraca, U. (Inst. Human Physiol., Univ. Messina, Italy). *J. Nutr.* 104(7):819-827, 1974.

5162 REUTILIZATION OF GUANIDO-LABELED ARGININE IN RAT LIVER PROTEINS AND THE INFLUENCE OF DIET. *(E.)* Nettleton, J. A.; Hegsted, D. M. (Harvard Sch. Public Health, Boston, Mass.). *J. Nutr.* 104(7): 916-921, 1974.

5263 ON THE REPRESSION OF RAT LIVER HMP SHUNT DEHYDROGENASES BY WHEAT GLUTEN. *(E.)* Livrea, G.; Carrozza, G.; Manasseri, L.; Muraca, U. (Inst. Human Physiol., Univ. Messina, Italy). *J. Nutr.* 104(7):957-961, 1974.

5264 INTERACTION OF ENDOGENOUS PEROXIDASE WITH FOREIGN PARTICLES IN PHAGOCYTIZING KUPFFER CELLS. *(E.)* Ogawa, K.; Minase, T.; Yokoyama, S.; Onoe, T. (Sapporo Med. Coll., Japan). *J. Reticuloendothel. Soc.* 15(4):255-265, 1974.

5265 STUDIES ON THE ROLE OF HEME IN THE REGULATION OF δ-AMINOLEVULINIC ACID SYNTHETASE DURING FETAL HEPATIC DEVELOPMENT. *(E.)* Woods, J. S. (Natl. Inst. Health, Research Triangle Park, N.C.). *Mol. Pharmacol.* 10(3):389-397, 1974.

5266 HUMORAL REGULATION OF LIVER REGENERATION AND TISSUE GROWTH. *(E.)* Morley, C. G. D. (Dept. Med., Univ. Chicago, Ill.). *Perspect. Biol. Med.* 17(3):411-428, 1974.

5267 EFFECT OF LIPID PEROXIDATION AND ITS INHIBITORS (BHA, BHT) ON THE DRUG METABOLIZING ENZYMES IN RAT LIVER MICROSOMES. *(E.)* Vainio, H. (Dept. Physiol., Univ. Turku, Finland). *Res. Commun. Chem. Pathol. Pharmacol.* 8(2):289-300, 1974.

5268 CALCIUM ACCUMULATION IN LIVER AND CALCIUM MOBILIZATION IN BONE OF LEAD-POISONED RATS. *(E.)* Yamamoto, T.; Yamaguchi, M.; Suketa, Y. (Shizuoka Coll. Pharm., Shizuoka Shi, Japan). *Toxicol. Appl. Pharmacol.* 27(1):204-205, 1974.

5269 PRELIMINARY STUDY OF IN VITRO AFLATOXIN B_1 METABOLISM BY HUMAN LIVER. *(E.)* Merrill, Jr., A. H.; Campbell, T. C. (Dept. Biochem., Virginia Polytech. Inst., Blacksburg). *Toxicol. Appl. Pharmacol.* 27(1):210-213, 1974.

5270 DIMETHYLSULFOXIDE INCREASES THE LETHALITY OF CCl_4 IN RATS BUT DECREASES ITS HEPATOTOXICITY. *(E.)* Mancini, R. E.; Kocsis, J. J. (Jefferson Med. Coll., Philadelphia, Pa.). *Toxicol. Appl. Pharmacol.* 27(1):206-209, 1974.

5271 CADMIUM INHIBITION OF HEPATIC DRUG METABOLISM IN THE RAT. *(E.)* Hadley, W. M.; Miya, T. S.; Bousquet, W. F. (Dept. Pharmacol. Toxicol., Purdue Univ., West Lafayette, Ind.). *Toxicol. Appl. Pharmacol.* 28(2):284-291, 1974.

5272 METABOLIC CHANGES IN "FROZEN-CLAMPED" LIVERS OF RATS CAUSED BY INGESTION OF POLYCHLORINATED BIPHENYLS. *(E.)* Mehlman, M. A.; Yin, L.; Nielsen, R. C. (Biochem. Toxicol. Br., FDA, Washington, D.C.). *Toxicol. Appl. Pharmacol.* 27(2):300-307, 1974.

5273 REDUCTION BY PRETREATMENT WITH DIBENAMINE OF HEPATOTOXICITY INDUCED BY CARBON TETRACHLORIDE, THIOACETAMIDE OR DIMETHYLNITROSAMINE. *(E.)* Maling, H. M.; Highman, B.; Williams, M. A.; Saul, W.; Butler, Jr., W. M.; Brodie, B. B. (Natl. Heart Lung Inst., Bethesda, Md.). *Toxicol. Appl. Pharmacol.* 27(2):380-394, 1974.

5274 EXPERIMENTAL HEPATIC PORPHYRIA INDUCED BY POLYCHLORINATED BIPHENYLS. *(E.)* Goldstein, J. A.; Hickman, P.; Jue, D. L. (Environmental Protection Agency, Chamblee, Ga.). *Toxicol. Appl. Pharmacol.* 27(2):437-448, 1974.

5275 PREVENTION AND TREATMENT OF CARBON TETRACHLORIDE HEPATOTOXICITY BY CYSTEINE: STUDIES ABOUT ITS MECHANISM. *(E.)* De Ferreyra, E. C.; Castro, J. A.; Diaz Gomez, M. I.; D'Acosta, N.; De Castro, C. R.; De Fenos, O. M. (no affil.). *Toxicol. Appl. Pharmacol.* 27(3):558-568, 1974.

5279 CONTROL OF INTESTINAL EPITHELIAL REPLACEMENT: LACK OF EVIDENCE FOR A TISSUE-SPECIFIC BLOOD-BORNE FACTOR. *(E.)* Clarke, R. M. (Univ. Nottingham Med. Sch., England). *Cell Tissue Kinet.* 7(3):241-250, 1974.

To investigate the possible role of systemic or local factors in the control of the presently unknown mechanism of small intestine epithelial regeneration, the small intestines of 38 male albino Wistar rats were transected in 2 places, (1) about 14% and (2) about 50% of the length from the pylorus. *In situ* continuity was re-established by suturing the proximal and distal ends. The excised small intestine segment, averaging 36% of the total length, had one end (proximal) closed off, and the other end (distal) sutured either to the *in situ* intestine forming an intestine-sac, or to the peritoneal lining of the abdominal wall, producing a skin-sac. There were no signicant differences among the groups in villus height, crypt depth, or crypt/villus ratio. On the 9th postoperative day, the cell production rate in squashes of micro-dissected whole crypts of Lieberkuhn was measured by mitotic blockade with demecolcine. The rate f cell production in unoperated and sham-operated ats was 30 cells/crypt/hr throughout the length of he small intestine. For the intestine *in situ*, the ate increased to an average of 46 cells/crypt/hr bove the anastomosis and to 54 cells/crypt/hr below t. At the blind end of the intestine-sac, the rate as 39 cells/crypt/hr, while at the blind end of the ac attached to the abdominal lining, the rate of ell production was only 16 cells/crypt/hr. This significantly lower cell production rate in the ntestine segment which was not in contact with ngesta is taken to be evidence of the importance of ocal, rather than systemic, blood-borne factors in he control of epithelial replacement.

5280 THE INFLUENCE OF VARIOUS CELL KINETIC CONDITIONS ON FUNCTIONAL DIFFERENTIATION IN HE SMALL INTESTINE OF THE RAT. A STUDY OF ENZYMES BOUND TO SUBCELLULAR ORGANELLES. *(E.)* De Both, N.J. an Dongen, J. M.; Van Hofwegen, B.; Keulemans, J.; isser, W. J.; Galjaard, H. (Erasmus Univ., Rotterdam, Netherlands). *Dev. Biol.* 38(1):119-137, 1974.

Maturation and aging of absorptive epithelial cells were investigated in isolated duodenal segments from Glaxo-Wistar rats. Cell kinetic data show that the epithelial cells originate in the lower half of the crypt and differentiate in about 10-12 hr in the upper half of the crypt. As functional absorptive cells they migrate to the top of the villi during 36 hr in normal rats and 48 hr in germfree rats. Activity of alkaline phosphatase, measured as a marker for microvilli, is absent in the crypt but increases linearly from the base of the villus to the tip. Nonspecific esterases, mainly localized in the endoplasmic reticulum, show increasing activity during cell maturation in the crypt and subsequent migration along the lower half of the villus; no further increase in activity occurs when the cell moves along the upper half of the villus. The longer life-span of villus cells in germfree Glaxo-Wistar rats does not result in higher esterase or alkaline phosphatase activity. An increased proliferative activity in the crypt, as present 72 hr after irradiation with 400 r, is accompanied by decreased esterase and alkaline phosphatase activity. The specific activity of enzymes bound to mitocondria or lysosomes (monamine-oxidase and β-N-acetylglucosaminidase, resp.) is not affected by changing crypt cell kinetics. Electrophoretic analyses of isolated cell compartments showed that the increase in esterase activity during normal differentiation and the decrease occurring after x-irradiation are due to changes in overall activity, not to the appearance or disappearance of specific isoenzymes. Electron microscopy showed gradual development of ultrastructural features during cell migration along the crypt, with drastic changes in structure occurring at the moment the cell enters the villus. Ultrastructural development was not influenced by increased proliferative activity in the crypt 72 hr after irradiation. Therefore, the decrease in enzyme activity is not related to ultrastructural changes.

5281 KINETIC EVIDENCE FOR THE PRESENCE OF TWO PROSTAGLANDIN RECEPTOR SITES REGULATING THE ACTIVITY OF INTESTINAL ADENYLATE CYCLASE SENSITIVE TO ENTEROTOXIN. *(E.)* Kantor, H. S.; Tao, P.; Kiefer, H. C. (Cook County Hosp., Chicago, Ill.). *Proc. Nat. Acad. Sci.* 71(4):1317-1321, 1974.

Kinetic behavior consistent with the presence of 2 independent, but simultaneously acting, regulatory effector sites for prostaglandins is presented for adenylate cyclase of rabbit intestinal epithelial cells. One site regulates activation of the catalytic site, while the other site regulates inhibition. A synthetic prostaglandin analogue, 7-oxa-13-prostynoic acid, is recognized at both sites in a concentration-dependent manner. At concentrations of 7-oxa-13-prostynoic acid less than 45 μg/ml, activation is seen, while at higher concentrations, inhibition occurs. Different naturally occurring prostaglandins appear to be site-specific. Prostaglandin E_1 gives only activation of the cyclase, while prostaglandin A_1 gives only inhibition of the activated cyclase. When saturating concentrations of prostaglandin E_1 are used to activate adenylate cyclase, no further activation by 7-oxa-13-prostynoic acid can be elicited, indicating that both molecules activate at the same site. The similarity of inhibition constants for both 7-oxa-13-prostynoic acid and prostaglandin A_1 suggests that the mode of binding is the same for both compounds and that they probably inhibit by acting at the same site. The inhibition by 7-oxa-13-prostynoic acid and by prostaglandin A_1 overrides enzyme activation produced by either *Escherichia coli* enterotoxin, prostaglandin E_1, or sodium fluoride, suggesting that in intestinal adenylate cyclase this site is the primary regulatory site for enzyme activity. These data suggest that sites exist on adenylate cyclase which would allow prostaglandins to serve as the intracellular messengers by which the cell controls its adenylate-cyclase-mediated response to extracellular stimulation, as with hormones.

5282 CORRELATIONS BETWEEN IONIC CONTENTS IN DIFFERENT REGIONS AND LAYERS OF INTESTINAL MUSCLE. *(E.)* Job, D. D.; Bloomquist, W. E. (Eli Lilly Co., Indianapolis, Ind.). *Am. J. Physiol.* 226(6):1496-1501, 1974.

In a systematic study of the ion content of cat intestinal muscle, different regions of the small intestine were compared and differences were also sought in the ion content of the two muscle layers. Entire intestinal tracts of cats of heterogeneous background and breed were excised, and segments from duodenum (1), jejunum (2), and ileum (2) were analyzed as to ion content of the circular and longitudinal muscle layers and of the 5 regions selected. Only sodium ions exhibited a statistically significant gradient down the intestine, with the ileum having a lower content than the duodenum. This gradient was present in both muscle layers separately and in combination with each other. Calcium was also significantly lower in the ileum than in the duodenum, but it did not decrease in a linear fashion and the difference was prevalent only in the longitudinal layer. In general, the longitudinal layer was higher in sodium, chloride, and calcium than the circular layer. Correlation coefficients computed for the various ions showed that sodium and calcium were significantly correlated; this is in keeping with current concepts of excitable membranes. Sodium and potassium, however, were less highly correlated. The finding of a high correlation between potassium and magnesium suggests a new relationship. The mechanisms involved in the differences of electrolyte concentrations and of interactions in the longitudinal and circular muscle layers as well as in the different regions for each layer remain obscure. Classical ionic mechanisms such as the one-for-one exchange of sodium and potassium and the sodium and calcium competition are not sufficient to explain all the correlations.

GENERAL

5296 HEPATIC PROTEIN BINDING OF FOLATE. *(E.)* Corrocher, R.; De Sandre, G.; Pacor, M. L.; Hoffbrand, A. V. (Inst. Med. Pathol., Trieste, Italy). *Clin. Sci. Mol. Med.* 46(4):551-554, 1974.

Binding of tritiated folic acid to liver cell cytoplasmic proteins of starved, male Wistar rats was studied *in vitro* and *in vivo* by Sephadex G75 column chromatography. *In vitro* studies revealed that folic acid is bound mainly in he Y and Z protein fractions, previously described s binding other organic anions, e.g., bilirubin r sulphobromophthalein. In the *in vivo* studies, t 10 min after injection of tritiated folic cid, radioactive folates in liver cytoplasm ere bound largely to X and Z protein fractions, ith a smaller fraction bound to the Y fraction. t 24 and 48 hr after injection, radioactive olates were bound largely to the X and Y protein ractions. The proportion of radioactive folate ound to the X fraction was greater *in vivo* than *n vitro*, and the proportion attached to Y and Z roteins was somewhat less. It is suggested that he Y and Z proteins or closely related proteins ay be involved in the transfer of folates from lasma to liver, the major store of folate in he body. It is suggested that competition etween folates and folate antagonists, for X, and Z proteins may be involved in the anti-olate action of the antagonists.

297 PRODUCTION AND PREVENTION OF FATTY LIVER IN RATS FED CLOFIBRATE AND OROTIC ACID DIETS ONTAINING SUCROSE. *(E.)* Novikoff, P. M.; Roheim, . S.; Novikoff, A. B.; Edelstein, D. (Albert Einstein oll. Med., Yeshiva Univ., Bronx, N.Y.). *Lab. nvest.* 30(6):732-750, 1974.

he prevention of fatty liver development by the simul-aneous administration of orotic acid and clofibrate, as investigated. Results of adding the agents to 6 iets fed to male Sprague-Dawley rats were determined y biochemical analysis of serum and hepatic lipids, mmunologic assays of plasma apoproteins, and morph-ologic studies of liver tissue. (I) Mild fatty liver as induced in the rats by feeding clofibrate as 0.25% f a high sucrose diet. While the liver triglyceride levels increased more than 2-fold, the plasma levels were lower than in either the high sucrose-fed or chow-fed controls. Examination of fine structure of the liver revealed that the smooth endoplasmic reticulum formed sheets or ribbons which were incompletely wrapped around lipid droplets and which were concentrated at the sinusoidal surfaces of all hepatocytes. It must be stressed that, as in control rats, the lipid accumulated outside the endoplasmic reticulum. Although the Golgi apparatus was normal, GERL (defined as a specialized region of endoplasmic reticulum [ER] and Golgi apparatus [G] where lysosomes [L] appeared) contained a great number of lipid particles in the process of degradation. A dramatic increase in peroxisome population was seen, as also in clofibrate addition to chow. (II) The addition of orotic acid as 1% of a high sucrose diet resulted in the development of very pronounced fatty livers. Hepatic triglyceride levels were about 9 times greater than normal by the 9th day, and about 20 times above normal by the 16th. Triglyceride levels in the plasma fell to less than 75% of control in 8 days, and at that time the apoprotein B component of plasma lipoproteins disappeared. Cytologically, the endoplasmic reticulum was broken into vesicles within which lipid accumulated. After 8 days, all signs of lipid transport via the endoplasmic reticulum and the Golgi apparatus to the space of Disse vanished. (III) When clofibrate and orotic acid were added to the diet simultaneously in the same proportions as indicated above, no fatty liver was produced. Liver triglyceride concentrations were lower than in sucrose controls until the 8th day; by the 16th day they reached sucrose control levels. Although plasma triglycerides were lowered, the total plasma apoprotein B remained at control levels. The relation of the endoplasmic reticulum to the Golgi apparatus was apparently normal, but GERL was more active in degrading lipids than in clofibrate-fed rats. The clofibrate effect on peroxisomes occurred even in the presence of orotic acid. As seen in these studies, it is not evident how clofibrate reverses the orotic acid development of fatty liver, but lipid particles move from the endoplasmic reticulum into the Golgi apparatus which secretes very low density lipoproteins into the plasma. Clofibrate also permits movement of lipid particles into GERL where it is catabolized, and this is consistent with the maintenance of normal levels of apoprotein B concentration in the plasma, as demonstrated in this investigation.

5298 INTERACTION OF SALICYLIC ACID WITH ADENOSINE AND ADENOSINE TRIPHOSPHATE: POTENTIAL MECHANISM OF INTENSIFYING ASPIRIN-INDUCED GI BLOOD LOSS. *(E.)* Sternson, L. A.; Coviello, D. A. (Univ. Illinois Med. Ctr., Chicago). *J. Pharm. Sci.* 63(6):966-968, 1974.

In this communication, results are reported on an investigation to establish a possible cause of aspirin-induced gastric or gastrointestinal bleeding, previously postulated as being due to either (1) local effect alone by contact of aspirin particles with the mucosa or (2) a combination of local and systemic effects. The latter was said to be due to the role of aspirin in reducing platelet aggregation through elimination of a 2nd wave of platelet accumulation induced by adenosine diphosphate. Results of this study revealed interaction between salicylic acid and adenosine or adenosine triphosphate to form complexes possessing greater surface activity. Because of this activity, reduction of platelet aggregation occurred, thus enhancing and prolonging the local effect. Spectrophotometric techniques were used to evaluate such formation of complexes at 296 nm in the presence of various concentrations of adenosine or adenosine triphosphate. The Benesi-Hildebrand equation yielded plots from which constants for the complex formations could be determined. Work is continuing to verify these findings and to investigate complex-formation with other adenine nucleotides.

5299 EFFECT OF GLUCAGON ON TOTAL BLOOD FLOW IN HEMORRHAGIC SHOCK. *(E.)* Darle, N.; Lim, Jr., R. C.; Blaisdell, F. W. (Univ. California Sch. Med., San Francisco). *Acta Chir. Scand.* 140(3): 217-225, 1974.

Since hemorrhage decreases the total liver blood flow and increases resistance to portal venous flow, this study was designed to investigate the effect of glucagon on total liver blood flow in hemorrhagic shock models using 13 adult mongrel dogs. When glucagon was given i.v. (50 μg/kg) 30 minutes after initiation of hemorrhagic shock, the total liver blood flow increased from 45 to 86 ml/min (95%) as measured by the Xenon-clearance method. Systemic arterial blood pressure levels, maintained close to 50 mm Hg, after hemorrhage remained unchanged in 1 dog; increased 5-20 mm Hg in 6; and decreased 2-10 mm Hg in 2 animals. The mean change in controls after administration of an equal volume of saline was a decrease from 51 to 50 mm Hg. A second 50 μg/kg i.v. injection of glucagon 2 hrs after shock increased total liver blood flow from 55 to 76 ml/min (46%) but the systemic arterial blood pressure showed a mean decrease from 53 to 50 mm Hg. The mean pressure was unchanged in the control group. Other parameters measured showed a significant increase in portal venous pressure after each glucagon administration; an increase in blood glucose after either glucagon or placebo injection; and a decrease in hematocrit in both groups during the study. The favorable effect of glucagon on total liver blood flow in hemorrhagic shock suggests that it may have a potential benefit on protecting the liver during shock. If this beneficial effect also occurs after correction of hypovolemia, the potential significance of glucagon therapy would be even greater. The observation in this study of a pronounced increase of total liver blood flow after transfusion of the glucagon-treated animals further indicates that there would be advantages to glucagon administration at the time of initiation of resuscitation, as the effects of transfusion might be augmented since splanchnic pooling should be lessened.

5300 BACTERIAL MICROFLORA OF THE UPPER GASTROINTESTINAL TRACT IN INFANTS WITHOUT DIARRHOEA. *(E.)* Challacombe, D. N.; Richardson, J. M.; Anderson, C. M. (Inst. Child Health, Univ. Birmingham, England). *Arch. Dis. Child.* 49(4):264-269, 1974.

A qualitative and quantitative study of the aerobic and anaerobic microflora of the upper gastrointestinal tract was undertaken in a group of 13 infants (5 girls and 8 boys, aged 2 weeks to 10 months). Bacteriological cultures from the nose and throat swabs showed a wide variety of organisms with coagulase-negative staphylococci appearing most frequently from nose cultures and *Streptococcus viridans* from the throat. Coliforms were present. Many of the nose and throat organisms were also isolated from the gastric juice. Coagulase-negative staphylococci, *Streptococcus viridans,* and coliforms were most frequently isolated. Duodenal juice showed marked bacteriological differences from gastric juice. In 7 of the 13 infants, it was sterile and coliforms were not isolated. In those in whom organisms were present, the types were similar to those found in the nose, throat, and stomach, thus suggesting contamination of the duodenum from higher up in the gastrointestinal tract. Under the effect of prolonged intubation, the total bacterial count rose only slightly from 6.8 to 7.02 $\log_{10}$/ml after 24 hr. However, a marked qualitative change in the microflora occurred during that time. The number of *Escherichia coli* in the duodenum, expressed as a percentage of the total amount, had increased after 9 hr and further increased by 24 hr. *Klebsiella* were also frequently isolated after 24 hr intubation. It is sugggested that prolonged intubation be avoided in future bacteriological studies.

5301 OBSERVATIONS ON THE PATHOGENESIS OF PERITONEAL ADHESIONS: A LIGHT AND ELECTRON MICROSCOPICAL STUDY. *(E.)* Milligan, D. W.; Raftery, A. T. (Dept. Anatomy, Univ. Leeds, England). *Br. J. Surg.* 61(4):274-280, 1974.

The development of peritoneal adhesions in 75 male Sprague-Dawley rats following abdominal surgery were observed by light and electron microscopy over a period up to 2 months postoperative. The method of multiple peritoneal trauma used here to induce adhesions yielded only one animal completely free from adherent complications. Essentially the changes which occurred were those which are seen in healing by fibrosis. However, in many areas of adhesion, numerous eosinophils were observed by electron microscopy, and in these areas little proliferation of fibroblasts was seen. Conversely in sites where fibroplasia and collagen formation were well advanced there were no eosinophils present. Since eosinophils have antihistamine activity, it is possible that they reduce the effect of the histamine released during the inflammatory process. Thus, local detoxification of histamine by eosinophils could indirectly reduce fibroblast proliferation while a new mesothelium is formed and thus prevent adhesion formation. Further investigation of the role of antihistamine drugs in the prevention of peritoneal adhesions is warranted on the basis of results of this study.

5302 PEROPERATIVE EVALUATION OF THE VIABILITY OF ISCHAEMIC COLON IN PRIMATES. *(E.)* Moossa, A. R.; Skinner, D. B.; Zarins, C. K.; Rhodes, B. A. (Univ. Chicago Hosp., Clin., Ill.) *Br. J. Surg* 61(4):301-304, 1974.

A quantitative method of predicting the eventual course of an ischemic colon segment found at laparotomy is presented here by use of an experimental model. Ischemic colitis was produced in 14 rhesus monkeys by complete vascular occlusion of the splenic flex for periods varying from 4 to 8.5 hr. Visual assessmen of bowel viability following revascularization was inaccurate in 10 monkeys. All the animals passed blood and mucus per rectum from 12-48 hr following the release of vascular occlusion. The amount of bleeding was variable but was most pronounced in the monkeys with marked reactive hyperemia. Two monkeys died 3 to 4 days following the experiment with gangrene of the splenic flexure and fecal peritonitis. Another monkey developed an external fecal fistula on the 5th day and was still excreting feces via the anterior abdominal wall 7 weeks later. Post-mortem examination demonstrated an internal fistula with the small bowel also present. Four monkeys had complete resolution from their ischemic episode; all had increased radioactivity uptake over the injured segment and both junctions. The remaining 7 showed varying degrees of colonic stricture and obstruction with or without local perforations, abscess and internal fistula formation. Quantitative measurement of reactive hyperemia using 3-4 mCi of ^{99m}techentium-tagged albumin microspheres with 15-30 m diameters (injected into the upper abdominal aorta via retrograd catheters) correlated well with autopsy findings. Marked hyperemic response suggested a transient form f ischemic colitis while a diminished or absent yperemic response predicted the development of stricures or gangrene of the colon segment.

303 METABOLIC AND CLINICAL EFFECTS OF PURE CRYSTALLINE 1α-HYDROXYVITAMIN D_3 AND 1α,25-DIHYDROXYVITAMIN D_3. STUDIES OF INTESTINAL CALCIUM TRANSPORT, RENAL TUBULAR FUNCTION AND BONE METABOLISM. (*E.)* Pechet, M. M.; Hesse, R. H. (Res. Inst. Med., Chem., Cambridge, Mass.). *Am. J. Med.* 57(1):13-20, 1974.

The effects of vitamin D_3 and two of its analogs, 1α-hydroxy-vitamin D_3 and 1α25-dihydroxy-vitamin D_3, were evaluated in a series of 3 investigations. In thyroparathyroidectomized rats, crystalline 1α-hydroxyvitamin D_3 (i.v. 0.1 μg) was more potent in increasing serum calcium concentration and urinary calcium and hydroxyproline excretion than 1α25-dihydroxy-vitamin D_3 (i.v. 0.1 μg). The effects of the former appeared and disappeared earlier. With either analog, concomitant administration of calcium augmented the decrease in urinary phosphorus. Both analogs were antagonistic to the phosphaturic action of parathyroid hormone (perfused i.v. as parathyroid extract 0.05 U/hr together with triiodothyronine 0.05 μg/hr). The analogs also showed a direct action on renal tubular reabsorption of phosphorus which is mediated by tubular calcium ion concentration. (2) In anephric rats, vitamin D_3 was effective in increasing serum calcium as were the analogs, but all 3 were ineffective in reestablishing a normal serum calcium level. These results are at variance with the prevailing concept that transformation of vitamin D_3 into an active metabolite is necessary for the expression of its biologic activity. (3) In patients with osteomalacia, crystalline 1α-hydroxy-vitamin D_3 induced a therapeutic response as shown by metabolic balance studies. In addition, bone biopsy examinations before and after therapy demonstrated mineralization of osteoid tissue as well as increases in both bone resorption and bone formation. In humans, 1α-hydroxy-vitamin D_3 is active when administered either orally or parenterally. Due to its shorter half-life, the rapid onset and cessation of activity of 1α-hydroxy-vitamin D_3 compared to vitamin D_3 should be of some benefit in the treatment of anephric patients and those with renal osteodystrophy, and that factor added to the analog's biologic activity portend less toxicity than that associated with the chronic administration of large doses of vitamin D_3.

5304 DISTRIBUTION OF BLOOD FLOW TO THE LAYERS OF THE SMALL BOWEL IN EXPERIMENTAL CHOLERA. *(E.)* Norris, H. T.; Sumner, D. S. (VA Hosp., Seattle, Wash.). *Gastroenterology* 66(5):973-981, 1974.

By analysis of multiexponential clearance curves recorded after intraarterial instillation of ^{133}xenon in saline into secondary ileal arcades in 12 dogs, the rate, distribution, and volume of blood flow to the layers of the small bowel were determined. Each clearance curve was factored into 4 components: countercurrent flow, mucosal-submucosal flow, muscular layer flow, and mesenteric fat layer flow. The same segment was studied empty in each animal, while producing choleraic effluent (cholera enterotoxin, 2 g dissolved in 30 ml distilled water), and while producing effluent with mean arterial blood pressure reduced 50% by phlebotomy. No significant difference in blood flow rate or volume was found under normotensive conditions when empty ileum was compared with choleraic ileum. Although marked changes in the volume and distribution of blood flow to the bowel wall occurred, these changes were no greater than those reported for shock alone. Thus it is suggested that the role of the microcirculation in experimental cholera is of secondary importance. It is further suggested that the primary effect of cholera enterotoxin is an epithelial phenomenon causing secretion of effluent.

5305 STUDIES ON THE DISTRIBUTION AND DEGRADATION OF HEPTADECAPEPTIDE, BIG, AND BIG BIG GASTRIN. *(E.)* Straus, E.; Yalow, R. S. (VA Hosp., Bronx, N.Y.). *Gastroenterology* 66(5):936-943, 1974.

Spaces of distribution and rates of degradation were determined for both unlabeled and radioiodinated gastrin peptides after pulse injection. The major forms of circulating gastrin, hepatadecapeptide gastrin, big gastrin, and big big gastrin had half-times for disappearance of approximately 3, 9, and 90 min., resp. Since the plasma concentration of each component under steady state conditions is determined not only by its secretion rate, but also by its distribution into extravascular spaces and its rate of degradation, these findings put into proper perspective the previously reported findings of the relative concentrations of the 3 components under different clinical conditions and in response to physiologic secretagogues and suppressants. For example, the strikingly long half-life of big big gastrin correlates well with its high relative concentration in the fasting state of several species. The observed differences in metabolism of the various hormonal forms makes clear the importance of determining the relative concentration of each component in the plasma in experiments dealing with the fate of endogenous gastrin.

5306 ESCAPE OF INTESTINAL RESISTANCE VESSELS TO ANGIOTENSIN II. *(E.)* McNeill, J. R. (Coll. Med., Univ. Saskatchewan, Saskatoon, Canada). *Can. J. Physiol. Pharmacol.* 52(3):458-464, 1974.

The escape phase of the intestinal resistance vessel response to infusions of angiotensin II was studied in pentobarbital-anesthetized cats using a technique which did not involve cannulation of the arterial supply to the intestine. During intravenous infusions of angiotensin, the escape was 30% of the peak response. The escape was not related to the increase in arterial pressure. In low doses, the escape during intra-arterial infusions was similar to that observed during intravenous administration. Graded increases in the infusion dose of angiotensin produced increasing vasoconstriction except at high doses. The results indicate that escape of the intestinal resistance vessels to angiotensin is only partial and that a significant vasoconstriction is maintained. The results are consistent with the postulated role of endogenous angiotensin in the mechanism of the intestinal vasoconstriction following hemorrhage.

5307 SPIRONOLACTONE AND TESTICULAR CYTOCHROME P-450: DECREASED TESTOSTERONE FORMATION IN SEVERAL SPECIES AND CHANGES IN HEPATIC DRUG METABOLISM. *(E.)* Menard, R. H.; Stripp, B.; Gillette, J. R. (Natl. Heart Lung Inst., Bethesda, Md.). *Endocrinology* 94 (6):1628-1636, 1974.

DIAGNOSTIC PROCEDURES

5365 SCINTIGRAPHY AS A SCREENING TEST FOR CARCINOMA OF THE PANCREAS. *(E.)* Watanabe, K.; Kawahira, K.; Matsuura, K. (Kyushu Univ. Sch. Med., Fukuoka, Japan). *Acta Radiol. (Diagn.) Stockh.* 15(1):57-64, 1974.

Pancreatic scintigraphy with ^{75}Se-selenomethionine was performed on 196 patients with various pancreatic disorders. The diagnosis of 83 of the cases was confirmed at surgery or autopsy and was suggested in 113 cases by symptoms, signs, and various laboratory examinations. Scintigrams were divided into 5 groups: localized defect, total defect, faint defects, displacement, and normal. Of the 39 patients with carcinoma of the pancreas, 22 had a localized defect in the pancreatic scintigram. A total defect occurred in 14 cases, indicating an abnormal scintigram in 92% of the cases. The scintigram was normal in 19 cases (44%). There was a localized defect in 8 (19%), faint defects in 7 (17%), and a total defect in 9(21%) of the 43 patients with pancreatitis. Normal scintigrams were obtained in 73 cases (89%), faint defects in 6 (7.3%), total defect in 2 (2.4%), and displacement in 1 (1.2%) of the patients later found to be normal. No patients with a localized defect were normal, and patients with carcinoma of the pancreas had a faint defect. Of the 100 patients with normal scintigrams, 73 were free of pancreatic disease. It is concluded that pancreatic scintigraphy is a useful means for diagnosing carcinoma of the pancreas.

5366 FACTORS INFLUENCING DUODENAL TRYPSIN LEVELS FOLLOWING A STANDARD TEST MEAL AS A TEST OF PANCREATIC FUNCTION. *(E.)* Zeitlin, I. J.; Sircus, W. (Univ. Strathclyde, Glasgow, Scotland). *Gut* 15(3):173-179, 1974.

The Lundh test was used to assess pancreatic function and to study disease and other pertinent factors which could influence the accuracy of diagnosis. This study was done on 98 patients with suspected pancreatic disease; retrospectively on 32 patients with already definitely diagnosed pancreatic status (15 negative and 17 diseased) and on 17 controls with non-pancreatic conditions such as anxiety states and ulcers (gastric or duodenal). The Wiggins trypsin assay used here on varying dilutions of crystalline trypsin gave a linear concentration/activity curve with a threshold of 50 µg/ml of crystalline trypsin. In the control group, trypsin values were similar to those found by other workers and were unaffected by the sex or age of the subjects. When used to assess the 32 already diagnosed patients, the test had a diagnostic success rate of 94%. Analysis of results from 98 patients with suspected pancreatic disease showed that trypsin levels were generally grossly reduced in patients with later established diagnoses of chronic pancreatitis or carcinoma of the head of the pancreas. The Lundh test distinguished nonpancreatic from pancreatic steatorrhea, except for possible false positive results in diabetes mellitus, bile duct obstruction, and villous atrophy.

5367 RAPID AND ACCURATE PREOPERATIVE DIAGNOSIS OF OBSTRUCTIVE JAUNDICE. UTILIZATION OF VISCERAL ANGIOGRAPHY AND TRANSHEPATIC CHOLANGIOGRAPHY. *(E.)* Kaplan, M. S.; Juler, G. L.; Stanton, W.; Eisenman, J. I. (Dept. Surg., Univ. California, Irvine). *Arch. Surg.* 108(6):825-829, 1974.

Percutaneous transhepatic cholangiography and selective visceral angiography were performed prior to surgery in 25 patients (44-84 years old, average 60.5 years) in order to identify possible malignancy and to locate the obstruction. Selective visceral angiography was diagnostic preoperatively in 60% of the patients and percutaneous transhepatic cholangiography in 76%. However, the combination of the 2 methods was diagnostic in 96% of the cases. Combination studies accurately predicted the cause in all 19 patients found to have a malignant tumor at laparotomy, although individual studies separately were positive in 72% with selective visceral angiography and 83% using percutaneous transhepatic cholangiography. The accuracy of these studies on obstructive jaundice contrasts sharply with the low yield of precise information obtained from chemical profiles, upper gastrointestinal tract series, barium enemas, and liver scans as to the cause of obstruction, especially malignancy, and its exact location.

5368 GALLIUM SCANNING IN ACUTE HEPATIC AMEBIC ABSCESS. *(E.)* Geslien, G. E.; Thrall, J. H.; Johnson, M. C. (Walter Reed Gen. Hosp., Washington, D.C.). *J. Nucl. Med.* 15(7):561-563, 1974.

Previous investigators concluded that hepatic amebic abscesses, unlike pyogenic abscesses, did not accumulate ^{67}gallium-citrate and included such cases among their correct negatives. In this report, 2 patients (male, 22 and 34-yr-old) with acute hepatic amebic abscess who showed identical patterns of ^{67}gallium-citrate accumulation in the periphery of the abscess cavity are described. Analysis of the ^{67}gallium distribution in comparison with the ^{99m}technetium-sulfur-colloid scans in the same patients indicated the probable site of localization as the region of hyperemia seen histologically and arteriographically, and also shed additional light on the pathophysiology of acute hepatic amebic abscesses. The results indicate that ^{67}gallium-citrate liver scanning performed after a radiocolloid study is a second modality which can increase the specificity and accuracy of diagnosis.

5369 LIVER SNAPS AND THE DETECTION OF CLINICALLY UNSUSPECTED LIVER METASTASES. *(E.)* Davies, R. J.; Vernon, M.; Croft, D. N. (St. Thomas' Hosp., London, England). *Lancet* 1(7852):279-280, 1974.

Since 50% of livers invaded by secondary tumors are normal in size, this study was designed to assess the value of preoperative radioisotope imaging of clinically normal livers in 46 patients with treatable proven carcinoma of the large intestine with no hepatomegaly. At operation or necropsy, 8 (17%) showed hepatic secondaries. Liver snaps detected single or multiple hepatic metastases in 7 of these patients; and in one patient, the snaps revealed a secondary liver tumor missed at surgery but confirmed at autopsy. Of the 8 patients with liver metastases, 7 were dead within 10 months of operation while over the same period of time, only 2 (5%) of those without liver secondaries had died. The radioisotope technique, involving the use of sulfur colloid labeled with technetium-99m and a Nuclear Enterprises gamma camera (whose images are called "liver snaps" at this hospital), gave a correct answer in 44 patients, an overall accuracy of 95%. This evidence implies that liver imaging is useful in the preoperative assessment of patients with cancer, even if the liver is clinically normal.

5370 MANOMETRIC ENDOSCOPIC RETROGRADE PANCREATOCHOLANGIOGRAPHY: TECHNIQUE, SIGNIFICANCE AND EVALUATION.

(E.) Kasugai, T.; Kuno, N.; Kizu, M. (Aichi Cancer Ctr. Hosp., Nagoya, Japan). *Am. J. Dig. Dis.* 19(6):485-502, 1974.

In endoscopic pancreatocholangiography, the precision of investigative results was retained but pancreatic damage due to excessive pressure was avoided by use of a recently developed manometer described here. This method permitted measurement and control of the injection pressure of the contrast medium. Of 687 attempted examinations on patients suspected of having pancreatic and/or biliary tract disease, 636 cannulations (92.6%) were successful. The desired duct or ducts were visualized in 611 cases (88.9%). The 636 cases cannulated consisted of 341 endoscopic pancreatographies, 64 endoscopic cholangiographies and 231 endoscopic pancreatocholangiographies. All malignant lesions diagnosed by the last method were proven at surgery or autopsy to be cancerous. Findings of pancreatic carcinoma were characterized by stenosis and obstruction of the main pancreatic duct and sometimes by a peripheral filling defect. The types encountered in order of frequency were: obstructed, stenosed, pancreatic-field-defect, and mixed types. Chronic pancreatitis was classified into 3 groups: minimal, moderate, and advanced pancreatitis, according to a grading of findings in endoscopic pancreatocholangiography. The main findings of minimal and moderate pancreatitis were pancreatectasis, while advanced disease showed opacification of the biliary system. There was a close correlation between histological and endoscopic grading of chronic pancreatitis. General results using this manometric method showed a decrease of 20% in elevation of serum amylase activity and a reduction in frequency of acinar filling. No clinical evidence of acute pancreatitis was seen. Although 3 cases of infection occurred (1 in liver abscess and choledocholithiasis and 2 in advanced pancreatic carcinoma of the stenosed type), no further complications of infection were observed when chemotherapeutics were mixed with the contrast material. These findings indicate that endoscopic pancreatocholangiography using the described monometric techniques is one of the most reliable procedures for the detection of diseases of the pancreatic and biliary systems.

5371 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY.

(E.) Liguory, C.; Gouerou, H.; Chavy, A.; Coffin, J. C. (Hosp. Rothschild, Paris, France). *Br. J. Surg.* 61(5):359-362, 1974.

Retrograde cholangiopancreatography was accomplished by direct non-operative injection of radio-opaque material through a cannula introduced at the duodenal papilla by means of a fiber-optic duodenoscope. This method achieved opacification of the bile ducts, the pancreatic duct or the entire biliary-pancreatic duct system in 392 (89%) of 439 patients in whom it was attempted. The desired ducts were opacified in 75% of cases; the bile ducts in 206 out of 278 and the pancreatic duct in 120 out of 161 cases. The anatomical conditions found were: 30% along common biliary-pancreatic channel; 28% short common biliary-pancreatic channel; 24% hepatopancreatic ampulla with 2 orifices; 18% duodenal papilla with 2 orifices; less than 1% no papilla, with 2 orifices on the duodenum. Morbidity resulting from the procedure consisted of infectious reactions in 20 out of 295 patient in whom the bile ducts were opacified as well as hyperamylasemia and abdominal pain in 28 out of 300 patients in whom the pancreatic duct was opacified. This method was of value in diagnosing the cause of cholestatic jaundice; in non-jaundiced subjects, it complemented or clarified inconclusive cholangiograms or cholecystograms obtained by other techniques. When dilated bile ducts appear, operation should not be delayed, otherwise there is a risk of cholangitis. Pancreatic carcinoma may be revealed by stenosis, partial or total, of the pancreatic duct or by filling defects in the pancreatic parenchyma, but chronic pancreatitis may also cause partial stenosis of the pancreatic duct. A filiform appearance of the pancreatic duct suggests chronic pancreatitis. The only complication after retrograde pancreatography is hyperamylasemia and its associated clinical manifestations. Possibly some method of controlling the injection pressure may reduce the incidence of this type of reaction.

5372 SIMPLIFIED CHOLANGIOGRAPHY USING IOGLYCAMIDE.

(E.) Parkin, G. J. S.; Herlinger, H. (Gen. Infirm., Leeds, England). *Gut* 15(4):268-272, 1974.

Intravenous cholangiograms were performed on 100 nonicteric patients (32 males, and 68 females, 19-81 yr old, mean age 54 yr) with the use of methylglucamine ioglycamide (Biligram). Fifty patients received 10.5 g of contrast medium, and 50 received 5.25 g injected evenly over 5 min. Side effects, reported in only 13% of the patients, were all mild consisting of urticaria (2), nausea (3), and metallic taste in mouth (8). Radiographs were taken 10, 30, 60, 90, and 120 min after injection and were assessed without the authors being aware of the dose of contrast medium injected. It was found that better statistically significant results were obtained using the higher dose. In patients with the gallbladder present, films taken at 60 and 90 min after injection gave the maximum available information in 97% of the cases. If the gallbladder has not become opacified by 60 min, cystic duct obstruction was indicated. Postcholecystectomy patients showed maximum available information in 95% of the cases in films taken at 30 min and 60 min after injection. The findings obtained in this study provide a simple procedure for intravenous cholangiography. Utilization of the radiographic room is not essential for the whole procedure, as the injection can be given in an anteroom, and the complete examination takes less than 10 minutes with the patient on the table.

5373 PANCREATOGRAPHY IN RELAPSING PANCREATITIS.

(E.) Arnesjo, B.; Kugelberg, C.; Tylen, U. (Univ. Hosp., Lund, Sweden). *Acta Chir. Scand.* 140(2):131-137, 1974.

To evaluate the significance of preoperative pancreatography, radiological findings were correlated with clinical and operative findings in 31 patients with relapsing pancreatitis and in 3 additional patients with inflammatory pancreatic disease. Radiological examinations were performed from the amputated tail surface in 28 cases and using the transampullary technique in 6 cases. On the basis of operative findings apart from pancreatography, the patients were classed as severe (14), moderate (9), and slight (8) pancreatitis cases. Pancreatography revealed 10-12 occurrences each of dilation, irregular walls, branch filling and strictures in the severe group; while the moderate cases exhibited only 4-6 occurrences of each of these abnormalities, and the slight group 0-3 each. Complete obstruction was found 3 times in both the severe and the moderate groups. Radiologically, the severity and frequency of these abnormalities were found to correlate well with the seriousness of the inflammatory process observed during operation. Cysts communicating with the duct and calculi were mainly demonstrated in the group of patients with severe pancreatitis. Results indicate that operative examination of the pancreas combined with pancreatography via the transected tail are of great value in the diagnosis and selective surgical management of patients with relapsing pancreatitis.

5374 MINUTE ENDOSCOPICAL FINDINGS OF DUODENAL MUCOSA USING THE DYE SCATTERING METHOD.

(E.) Kohli, Y.; Nakajima, M.; Ida, K.; Kawai, K. (Kyoto Pref. Univ. Med., Japan). *Endoscopy* 6(1):1-6, 1974.

The duodenoscopic application of the direct dye scattering method was used to identify minute lesions of the duodenal mucosa in 173 patients. The patient group included 54 cases of single round duodenal ulcers and scars, 17 cases of linear ulcers, 75 cases of multiple ulcers, 11 cases of duodenal erosions, 5 cases of polyploid lesions, and 11 cases of normal duodenal mucosa. The effect of the dye scattering method was insufficient to observe minute findings in the duodenal mucosa in or around the lesion in 5 of the 173 cases. Minute findings were either partly or completely observed in 130 (75.1%) of the cases, and information unobtainable by usual endoscopy was obtained in 38 cases (22.0%). Not only could ulcers or ulcer scars be clearly visualized, but also the villous pattern of the duodenal mucosa. Around the ulcer the villi became more and more irregular in shape and size, showing also minute defects and microerosions. Minute elevations were due to hyperplasia of Brunner's glands. The frontal viewing duodenoscopes seemed superior in recognizing this microarchitecture to the side-viewing type.

5375 CHOLECYSTOKININ CHOLECYSTOGRAPHY: CONTROLLED EVALUATION IN THE DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH POSSIBLE ACALCULOUS GALLBLADDER DISEASE.

(E.) Dunn, F. H.; Christensen, E. C.; Reynolds, J.; Jones, V.; Fordtran, J. S. (Univ. Texas Southwestern Med. Sch., Dallas). *JAMA* 228(8):997-1003, 1974.

X-ray films of the opacified gallbladder were taken at intervals following i.v. injection of cholecystokinin (75 Ivy dog U) in 44 control subjects and in 49 patients with biliary colic (aged 22-61 yr) and in 25 patients with dyspepsia (aged 17-84 yr). Even though all the patients showed histories suggestive of gallbladder disease, the routine cholecystography in each was normal. Abnormal X-ray results were found in 30-40% of the patients, but the incidence of "false-positive" results was high in the control group (14-36%, according to 3 radiologists). Cholecystectomy was performed in 29 cases due to continued pain. The clinical response to surgical treatment and the histologic findings in the resected gallbladders were similar in patients with normal and abnormal preoperative cholecystokinin cholangiographic studies. It is concluded that, as currently used, cholecystokinin cholecystography is not helpful in the diagnosis and management of patients with suspected acalculous gallbladder disease.

5376 AMYLASE ISOENZYMES DURING VIRAL INFECTIONS OF THE PANCREAS AND SALIVARY GLANDS.

(E.) Ross, M. E.; Wolf, R. O.; Notkins, A. L. (Natl. Inst. Dental Res., Natl. Inst. Hlth., Bethesda, Md.). *J. Lab. Clin. Med.* 83(5):750-756, 1974.

Since viral infections produce severe alterations in total serum amylase, this study of amylase levels related to pathologic changes as well as measurement of serum pancreatic and parotid amylase concentrations with disease was initiated. Infection of DBA/2 mice with Coxsackie B viruses produced severe acinar pancreatitis and a 5-fold rise in serum amylase levels by the 2nd day. Concurrently, pancreatic amylase content fell, and remained less than 5% of normal for several months. Infection produced permanent, extensive necrosis of pancreatic acinar tissue. Analysis of serum isoamylases by polyacrylamide gel electrophoresis revealed that during the acute phase of the infection, the hyperamylasemia (10 times normal isoamylase level) was predominatly pancreatic in origin. No rise in salivary isoamylase was seen. After infection, the amylase level in the serum returned to normal, but isoamylase analysis detected a marked decrease in the pancreatic isoamylases. In contrast, the M variant of encephalomyocarditis (EMC) virus produced severe beta-cell damage but relatively little damge to the acinar cells of the pancreas and parotid glands. Serum amylase levels rose only slightly during the acute phase of the infection but were depressed for prolonged periods thereafter. Analysis of serum isoamylases revealed decreased levels of both pancreatic and salivary isoamylases. These results indicate that quantitation of serum isoamylases might be a useful tool for detecting and differentiating pancreatic and parotid gland diseases.

5377 USE OF THE ^{198}AU LIVER SCAN IN ASSESSING THE THERAPEUTIC EFFECT OF PENICILLAMINE IN WILSON'S DISEASE. *(E.)* Chajek, T. (Hadassah Univ. Hosp., London, England). *Postgrad. Med. J.* 50(582): 207-208, 1974.

In a 14-yr-old girl Wilson's disease was found to be the cause of an active cirrhosis diagnosed months previously. The diagnosis of Wilson's disease was confirmed by the finding of bilateral Kayser-Fleischer ring on slit lamp examination. Repeated examinations revealed a serum ceruloplasmin concentration of 16-18 mg/100 ml; 24-hr urinary copper excretion was 330 μg. ^{198}Au liver scan showed very low uptake by the liver, and a high ^{198}Au concentration in the enlarged spleen. Treatment with D-penicillamine (2 g/day) caused marked clinical and biochemical improvement. The spleen decreased in size, liver function tests improved, jaundice and ascites disappeared, and esophageal varices diminished. Repeated ^{198}Au liver scans revealed increased liver uptake of ^{198}Au, presumably a reflection of improved liver circulation and reduction in portal hypertension. Repeated liver scanning in Wilson's disease patients may provide another easy and safe test for evaluating the effect of penicillamine therapy, especially in patients in whom repeated liver biopsy may be contraindicated.

5378 RETROGRADE PANCREATOCHOLANGIOGRAPHY BY ENDOSCOPIC CATHETERIZATION OF THE PAPILLA OF VATER. *(Fr.)* Liguory, C.; Bitoun, A.; Bognel, J. C.; Coffin, J. C.; Gouerou, H.; Chavy, A. (no affil.). *Vie Med.* 54(36):4583-4604, 1973.

GASTROINTESTINAL DISEASES

ESOPHAGUS

5422 THE DISTAL ESOPHAGEAL SPHINCTER AND ITS RELATIONSHIP TO GASTROESOPHAGEAL REFLUX. *(E.)* Thurer, R. L.; Demeester, T. R.; Johnson, L. F. (Navy Regional Med. Ctr., Honolulu, Haw.). *J. Surg. Res.* 16(4):418-423, 1974.

In this study pH and manometric measurements across the distal esophageal sphincter were obtained on 159 patients. Both antegrade and retrograde passage of the catheter assembly were made in 77 patients. The remaining 82 patients had only retrograde studies. The results indicate the variability of sphincter data when obtained by antegrade and retrograde techniques. Sphincter data were evaluated against the standard acid reflux test. It was thus shown that the distal esophageal sphincter resting pressure is quantitatively related to reflux and that the majority of patients who reflux have distal esophageal sphincter resting pressures greater than 10 mm Hg. The presence of reflux was related to the antegrade pH gradient and the antegrade modified Tuttle test. The quantitative character of these measurements make their clinical use for determining the presence of reflux impractical. It was concluded that esophageal manometry is clinically useful only in locating the position of the sphincter prior to doing the standard acid reflux test, evaluating the presence of motility abnormalities, and determining the effectiveness of both medical and surgical therapy designed to increase sphincter pressure.

5423 PATHOPHYSIOLOGY OF ACHALASIA OF THE CARDIA. *(E.)* Misiewicz, J. J. (Central Middlesex Hosp., London, England). *Postgrad. Med. J.* 50(582): 207-208, 1974.

The symptoms and signs of achalasia are due to the loss of ganglion cells in the body of the esophagus, leading to dilation and loss of peristaltic activity. The data pertaining to the lower esophageal sphincter are still somewhat conflicting. The ganglion cells may be absent, but pharmacological evidence suggests denervation to be preganglionic. The classic view of a normotensive, nonrelaxing achalasic sphincter has been challenged by manometric studies performed with perfused open-ended tips. Studied with this technique, the achalasic sphincter appears to be markedly hypertensive and to retain a limited, but distinct ability to relax. Despite high sphincteric pressures, serum gastrin levels were normal in 19 patients with achalasia, and the sphincter relaxed when the gastric antrum was acidified. Supersensitivity of the achalasic sphincter to exogenous gastrin I was also demonstrated.

5424 THE ASSOCIATION BETWEEN WEBS, IRON AND POST-CRICOID CARCINOMA. *(E.)* Chisholm, M. (Roy. South Hants Hosp., Southampton, England). *Postgrad. Med. J.* 50(582):215-219, 1974.

Over a 15-yr period a follow-up study was made of 72 patients with post-cricoid webs. More than ½ had iron deficiency anemia at diagnosis, a further 10% were iron deficient on investigation, and a past history of iron deficiency anemia was noted in 21%. Thus, a definite link between iron deficiency and a post-cricoid web was established in 88%. Associated conditions in the 72 patients included a high incidence of thyroid disease and malignancies (15% each). Of the 11 patients with malignancies, 6 had a carcinoma in the upper gastrointestinal tract. In a prospective study, patients with iron deficiency anemia (168), healthy controls (98), and patients with a variety of disorders previously shown to coexist with a post-cricoid web (166) were examined for evidence of a web by cinefluorography of swallowing. Only 10% of patients with iron deficiency had post-cricoid webs, but 27 of 32 patients with a web had evidence of iron deficiency. Web patients had increased frequency of angular stomatitis and edentia, thyroid disease, and thyroid cytoplasmic antibodies compared to patients with iron deficiency anemia without a web. These studies support an association between iron deficiency, post-cricoid webs, and post-cricoid carcinoma. The mechanism by which these changes are produced is not yet understood.

STOMACH

5441 RECURRENT ULCERATION AFTER GASTROENTEROSTOMY OR PYLOROPLASTY WITH COMPLETE AND INCOMPLETE VAGOTOMY. *(E.)* Gillett, D. J.; de Burgh, M. M. (Repatriation Gen. Hosp., Concord, New South Wales, Australia). *Am. J. Surg.* 127(6):650-652, 1974.

The relative value of gastroenterstomy and pyloroplasty as drainage procedure after vagotomy was examined in 191 patients with a mean follow-up period of more than 4 years. The over-all recurrence rate was 7% (13 of 171), with 5% recurrence (7 of 124) after gastroenterostomy and 9% (6 of 67) after pyloroplasty. In patients who had incomplete vagotomy, the rate of recurrent ulceration was 10% (3 of 30) after gastroenterostomy and 17% (3 of 18) after pyloroplasty. These figures fail to show any significant difference between rates of recurrent ulceration after either drainage procedure, even with incomplete vagotomy. Therefore, there is no reason to prefer one procedure over the other on a basis of recurrent ulceration.

5442 THE EXPERIMENTAL PRODUCTION OF GASTRIC ULCERS BY INDUCED MUSCLE SPASM. *(E.)* Qvist, G.; Dormandy, J.; Brown, C.; Slome, D.; Scott, G. B. D. (Roy. Coll. Surg. England, London). *Br. J. Surg.* 61(4):259-263, 1974.

A technique is described for the experimental production of gastric ulcers in dogs, by producing forceful spasmodic and longer localized muscle contractions due to intermittent stimulation by means of electrodes implanted in the stomach muscle. The stimulator is attached to the animal's back. Following some early technical failures due to stenosis and stasis, an adequate stimulus was applied for 2-3 weeks in 16 animals. In 13 cases macroscopic lesions developed in the stimulated area, varying from frank perforation to superficial erosions. Confirmation was provided by barium meal examinations and histologic observation. The responsible mechanism may be a localized ischemia as seen by blanching of the contracted area due to the increased strength and duration of the muscle spasms, thereby predisposing to necrosis and ulceration of the mucosa and the more superficial layers of the stomach wall.

5443 MUCOUS SUBSTANCE AND ENZYME HISTOCHEMISTRY OF NON-NEOPLASTIC AND NEOPLASTIC GASTRIC EPITHELIUM IN MAN. *(E.)* Kobori, O.; Oota, K. (Fac.

Med., Univ. Tokyo, Japan). *Acta Pathol. Jap.* 24(1): 119-130, 1974.

Neoplastic gastric epithelium from resected stomachs of 100 patients with gastric carcinoma was examined and gastric tissue strips were analyzed for 7 kinds of enzymes, including dehydrogenases, phosphatases, and lysosomal enzymes. Non-neoplastic gastric epithelium and other tissue from 20 stomachs resected from ulcer patients served as controls. Histologically, the tumors consisted of 30 well-differentiated, 47 moderately differentiated, and 23 undifferentiated adenocarcinomas. Since it has been shown that some of the well-differentiated gastric carcinomas contained epithelial elements histocytologically closely resembling intestinal epithelial cells, e.g. brush borders, the concept of intestinal and diffuse types of gastric carcinoma was postulated. Enzyme analysis here showed that combination of alkaline phosphatase and aminopeptidase was invariably positive in intestinal epithelium, benign or malignant, and was never found under other conditions. On the basis of this, the 100 gastric carcinomas were divided into 44 intestinal epithelial and 56 non-intestinal epithelial types. The percentages of the 44 histochemically-classified intestinal type carcinomas were correlated to the tubular structural differentiation of the neoplasms as follows: 46.7% of the histochemically identified intestinal adenocarcinomas (14 of 30 morphologically well-differentiated carcinomas) showed exclusively papillo-tubular formation; 43.5% (10 of 23 undifferentiated) had an infiltrating or cord-like pattern; and 42.6% (20 of 47 moderately differentiated) exhibited a mixture of the above 2 tubular structural arrangements. There is, apparently, no direct correlation between enzymatic characteristics as to intestinal or non-intestinal types and morphological tubular differentiation. It is suggested that quantitative studies of products of human neoplasms, i.e. enzymes or hormones, can clarify tumor cell differentiation better than morphological or histological examination.

5444 THE DETECTION OF AN ANTIGEN PRESENT IN GASTRIC CARCINOMA. *(E.)* Hocking, W.; Epps, A. C.; Akdamar, K. (Tulane Univ. Sch. Med., New Orleans, La.). *Am. J. Dig. Dis.* 19(6):537-546, 1974.

Studies to detect antigenic sulfoglycoproteins using indirect immunofluorescence and counterimmunoelectrophoresis were performed on 32 gastric biopsies and on 36 gastric aspirations. Patients with gastric carcinoma, lymphoma, benign gastric lesions, as well as those without evidence of gastric disease were examined. Specific antisera to sulfoglycoproteins found in aspirates of gastric carcinoma patients were produced in rabbits and later absorbed to increase specificity. Fluorescent staining of the cell membrane was observed in tissues of gastric carcinoma patients. In biopsies from patients with other forms of gastric pathology as well as normal gastric mucosa, a more diffuse fluorescent staining was noted. Counterimmunoelectrophoresis demonstrated a single precipitin band in all aspirates from patients with gastric carcinoma, in 1 patient with lymphoma, and in 1 patient with gastric polyps showing atypical hyperplasia. The remaining aspirates produced no precipitin bands. Results of this study suggest that counterimmunoelectrophoresis has greater diagnostic value than the indirect immunofluorescent technique for the detection of gastric sulfoglycoproteins, and therefore this method may prove useful in the diagnosis of gastric carcinoma. The high rate of positivity in patients with confirmed gastric carcinoma and the low rate in patients without carcinoma indicate that detection of gastric sulfoglycoprotein may be a useful adjunct to the procedures currently available for the diagnosis of gastric lesions. Detection of sulfoglycoprotein may prove particularly valuable in the distinction of benign gastric ulcers from ulcerated carcinoma.

5445 IMMUNOREACTIVE GASTRIN COMPONENTS IN HUMAN SERUM. *(E.)* Rehfeld, J. F.; Stadil, F.; Vikelsoe, J. (Bispebjerg Hosp., Copenhagen, Denmark). *Gut* 15(2):102-111, 1974.

Sephadex gel filtration and aminoethylcellulose chromatography were used to determine the apparent molecular size and charge of immunoreactive gastrin components in sera from patients with pernicious anemia or gastrinomas (the Zollinger-Ellison syndrome). The following serum components were identified: (1) a monophasic component I similar in size to proinsulin which was converted into "little" gastrin I by trypsin digestion; (2) a biphasic component II, corresponding to "big" gastrins I and II (Gregory and Tracy); (3) a biphasic component III corresponding to "little" gastrins I and II (Gregory and Tracy); and (4) a biphasic component IV, corresponding to "minigastrins" I and II (Gregory and Tracy). "Big, big" gastrin, a plasma component found in the void volume of the Sephadex G-50 column by Yalow and Berson was undetectable in the sera investigated. A component in gastrinoma and antral mucosa extracts corresponding in size to "big, big" gastrin was detectable by the assay; the "big, big" gastrin fraction from gastrinoma tissue was heterogenous, with components of apparent molecular weights of 30,000-100,000. It is concluded that serum gastrin circulates in the form of at least 4 components, of which the 3 smaller ones are in pairs.

5446 DUODENO-GASTRIC REFLUX AND ACID SECRETION IN PATIENTS WITH SYMPTOMATIC HIATAL HERNIA. *(E.)* Stol, D. W.; Murphy, G. M.; Collis, J. L. (Univ. Hosp., Rotterdam, Netherlands). *Scand. J. Gastroenterol.* 9(1):97-101, 1974.

Duodeno-gastric reflux and acid secretion were studied in 32 symptomatic hiatal hernia patients and in 13 controls. The duodeno-gastric reflux was measured by colorimetric determinations of bile acid concentrations in fasting gastric juice. Acid secretion was measured by titration of gastric juice before and after stimulation of the subjects with pentagastrin. The concentration of total bile acids in the stomach was increased in the hiatal hernia patients, indicating the presence of duodeno-gastric reflux.

Elevation of the basal acid output also was prounced in the hiatal hernia group, with a slight increase in peak acid output. An increase in both bile reflux and basal acid output appeared to be correlated with severity of the illness. A preliminary examination of the individual bile acid fractions present in the gastric juice suggested that samples from patients with stricture formation contain a smaller proportion of glycine conjugates than those from control subjects.

5447 INTESTINAL METAPLASIA OF THE GASTRIC MUCOSA. ENDOSCOPIC RECOGNITION AND REVIEW OF THE LITERATURE. *(E.)* Korn, E. R. (Scripps Clin., Res. Fdn., La Jolla, Calif.). *Am. J. Gastroenterol.* 61 (4):270-275, 1974.

Endoscopic recognition of intestinalization of the gastric mucosa (the presence in the gastric mucosa of intestinal epithelium) is advocated, using the Olympus GIF fiberoptic gastroscope with the distal ends of its fiberoptic bundles recessed a short distance behind the end of the scope. This enables the observer to obtain excellent close-up views of fine mucosal detail, including the villous pattern of the duodenal mucosa. In a patient with gastric ulcer, gastroscopic examination of mucosa surrounding the ulcer appeared identical to that of normal duodenal mucosa, and gastric biopsy study corroborated the intestinalization. If the ulcer is a metaplastic lesion, the stimulus favoring differentiation in the direction of intestinal epithelium is chronic irritation, such as is seen in gastritis. The frequency of this change in benign lesions is much less than in carcinoma, and the frequency of intestinalization also increases with age and with the extent of gastric mucosa studied. The relationship between gastric carcinoma and intestinalization of the gastric mucosa has been emphasized by the high frequency of association of these 2 lesions. Sixty to 100% of patients with carcinoma of the stomach have had associated intestinalization. The distribution of intestinal metaplasia in the stomach is similar to that of carcinoma. Fifty percent of all invasive carcinomas of the stomach are of the intestinal cell type. However, metaplastic epithelium has some variability in mucin reactions and ultrastructure similar to, but less extensive than, tumor cells. Histochemistry has also demonstrated the similarity of the metaplastic cells to those of normal small intestine. The ability to recognize areas of intestinal metaplasia endoscopically and to direct biopsy forceps to these areas are important in better delineating the identification of this lesion.

5448 FACTORS INFLUENCING THE DEVELOPMENT OF INDOMETHACIN-INDUCED INTESTINAL ULCERS IN THE RAT. (38060) *(E.)* Volterra, G.; Pisanti, N.; Meli, A. (Res. Labs., A. Menarini Pharmaceuticals, Florence, Italy). *Proc. Soc. Exp. Biol. Med.* 146(1): 146-152, 1974.

The influence of sesame oil, a fat-free diet, and increased bile flow on indomethacin-induced intestinal ulcers was studied in male and female Wistar-Morini albino rats. A program of fasting 17 hr before and 7 hr after indomethacin was adopted for maximum protection against ulceration. Indomethacin, suspended in an aqueous vehicle, was administered by gavage at several dose levels in a constant volume of 5 ml/kg. 1-Phenylpropanol (400 mg/kg) was solu-suspended either in sesame oil or in an aqueous vehicle and administered in a constant volume (5 ml/kg) 4 hr after indomethacin as a choleretic agent. The animals were fed either a regular diet or a fat-free diet over a 10-day period before the experiments. Starvation significantly reduced the incidence of indomethacin-induced intestinal ulcers in the rats fed a regular diet, but the feeding schedule did not affect ulcer formation in those fed a fat-free diet. The incidence of indomethacin-induced intestinal lesions was lower in the latter animals. Independent of feeding schedule and nature of diet, 1-phenylpropanol in aqueous suspension failed to enhance the ulcerogenic properties of indomethacin but when given as an oily solution, 1-phenylpropanol promoted ulcer formation in test animals over and above that observed following the administration of sesame oil. Within the fat-free diet groups, sesame oil potentiated ulcer formation both in fasted and unfasted animals, but in the regular diet group only during fasting periods. Thus, the effects of sesame oil facilitation and fat-free diet prevention on indomethacin-induced intestinal ulcers are independent of bile flow and/or composition as shown by results here.

5449 HISTOLOGY AND HISTOGENESIS OF EARLY GASTRIC CARCINOMAS WITH FLAT MUCOSAL ELEVATIONS. *(E.)* Nagayo, T. (Aichi Cancer Ctr., Nagoya, Japan). *Acta Pathol. Jap.* 24(2):249-272, 1974.

To differentiate between early gastric carcinomas and non-malignant atypical epithelial growths with similar gross and microscopic characteristics, 648 cases of early gastric carcinoma were examined grossly and histologically. Circumscribed, sessile, and flatly elevated early carcinomas were found in 5.5% of these. Most of the lesions showed highly differentiated, tubular adenocarcinomas composed of columnar epithelium and accompanied by pronounced intestinal metaplasia in the cancer-bearing pyloric mucosa. Histological study showed that the elevated lesions were not due to primary growth of the carcinoma but rather to reactive growth of the non-neoplastic gastric mucosa in response to the developing carcinoma. Occasionally, the histological features of the lesions seemed to lie between benign and malignant types. These were termed border-line lesions; in general, they were smaller than carcinomas. Microscopically, upper layers of the elevated mucosae always contained diffuse but regularly placed, darkly stained tubules running vertically to the muscularis mucosae. In lower layers, cystic dilations of the gastric glands were almost always visible among non-atypical orthochromatic hyperplastic glands. Downward proliferation of atypical tubules could be seen but, unlike in cases of well-differentiated adenocarcinomas, the layers of the affected mucosa were infrequently occupied by atypical tubules. The nucleo-cytoplasmic ratio was smaller and cytoplasm was more clearly recognizable along the glandular lumina in the epithelium of the border-line lesion than in the carcinomas.

5450 ANGIOGRAPHY IN GASTRIC TUMOURS. *(E.)* Efsen, F.; Fischerman, K. (Rigshosp., Copenhagen, Denmark). *Acta Radiol. [Diagn.] (Stockh.)* 15(2): 193-197, 1974.

Preoperative celiac and superior mesenteric angiographies were carried out in 15 patients (44-82 yr old) with histologically verified gastric tumors. No growths below 3 cm in diameter were present in this series; and in all sizes observed, the most constant angiographic sign was a change in the caliber of small arteries and parenchymatous accumulation of contrast medium. Gastric tumors more than 5 cm in diameter had more extensive angiographic changes than those of smaller diameter; no relation was noted between macroscopic and angiographic sizes of the tumors. Sarcomatous tumors (reticulosarcomas and leiomyomas) presented few changes compared with carcinomas, but different types of carcinomas could not be identified angiographically. The angiographies did not supply information regarding tumor operability. Thus, it was not possible, even by a detailed assessment of the angiographic changes, to estimate the size or the operability of a gastric neoplasm.

5451 CARCINOMA OF THE STOMACH FOLLOWING PARTIAL GASTRECTOMY FOR BENIGN GASTRODUODENAL LESIONS. *(E.)* Nicholls, J. C. (Charing Cross Hosp. (Fulham), London, England). *Br. J. Surg.* 61(3):244-249, 1974.

Thirty-six patients (30 men and 6 women, aged 33-70 yr) with gastric carcinoma who had previously undergone partial gastrectomy for benign lesions were studied. Of these patients, 28 underwent the gastrectomy at St. James' Hospital, London. Of the 36 patients, the original pathology was gastric ulcer in 25 cases, duodenal ulcer in 6, duodenal diverticulum in 1, gastric and duodenal ulcer in 1, and unknown in 2 cases. Based on this series, the incidence of carcinoma following partial gastrectomy is 1 in 76 gastric ulcer patients compared with 1 in 865 duodenal ulcer patients. The average time between gastrectomy and diagnosis of carcinoma was 8½ yr in the St. James' group and 13 yr for the 8 patients treated elsewhere. Only 2 of the 23 who underwent surgery for their carcinoma survived for more than 5 yr. Partial gastrectomy for gastric ulceration does not protect against subsequent gastric cancer; however, it will remove treatable early carcinoma, which may easily be mistaken for a benign gastric ulcer. Despite the poor prognosis, thorough investigation of the postgastrectomy patient with early surgical treatment is warranted by the occasional long-term survivor.

5452 DOUBLE PYLORUS: A HYPOTHESIS CONCERNING ITS PATHOGENESIS. *(E.)* Farack, U. M.; Goresky, C. A.; Jabbari, M.; Kinnear, D. G. (Montreal Gen. Hosp., Quebec, Canada). *Gastroenterology* 66(4): 596-600, 1974.

Two cases of double pylorus are reported, one involving a complete double pyloric canal in a 75-yr-old woman and the other a gastro-gastric channel in a 30-yr-old man. The former patient presented with upper gastrointestinal bleeding but with no epigastric pain, vomiting, or history of ulcer disease. Gastroscopy revealed two channels between the stomach and duodenum, with a characteristic septal impression between the two. A nonbleeding ulcer was seen in the inferior canal. A biopsy taken from the proximal end of the tissue bridge between the two channels showed intestinalization of the mucosa. Review of previous radiographs indicated that the lesion had been acquired. The patient was discharged on an ulcer diet and decreased dose of the prednisone. The second patient was admitted to the hospital because of recurrent hematemesis, with nausea, epigastric fullness, and dull epigastric pain. An upper gastrointestinal series revealed a distended stomach with a prepyloric ulcer and an ulcer at the distal lesser curve. Endoscopy demonstrated two openings, at the distal lesser curvature, separated by a tissue bridge. Continuity between the two openings was demonstrated, as was a channel connecting the two ulcers. The connective channel was lined by normal gastric mucosa. The patient has been well since subtotal gastrectomy. It is suggested that the formation of a double pylorus involves an activation of a prepyloric ulcer, deep penetration into the wall of the pylorus, and perforation into the duodenum.

5480 GASTRIC CLEARANCE OF SERUM ALBUMIN IN NORMAL MAN AND IN CERTAIN GASTRODUODENAL DISORDERS. *(E.)* Brassinne, A. (Univ. Liege, Baviere Hosp., Belgium). *Gut* 15(3):194-199, 1974.

The measurements of the passage of albumin from the plasma to the gastric juice in the basal secretory state and during stimulated secretion in 41 normal volunteers (35 males, 6 females, 21 to 29 yr old) and in 19 patients are presented. There was no correlation between acid output and albumin leakage into the stomach in the normal volunteers as estimated from the measurement of non-dialysable radioactivity of the gastric juice after i.v. injection of radioiodinated serum albumin (100 µCi). For the 41 normal subjects, gastric clearance of serum albumin at the second hour was significantly lower than at the first hour with the respective means 1.71 ml/hr and 2.07 ml/hr. The serum albumin loss into the stomach amounted to 11.3% of its catabolism in normal man. In the 7 patients with duodenal ulcer, gastric clearance and catabolism of serum albumin were not significantly different from the control group. The same was true with the 3 gastric ulcer patients. In pernicious anemia (7 patients), the gastric clearance of serum albumin was significantly greater (3.72 ml/hr) than in the normal group. It accounted for the greater fractional catabolic rate of serum albumin in this disease and a lower level of albumin in serum. In the case of giant hypertrophic gastritis, albumin clearance was 6.22 ml/hr. It fell to 2.59 ml or 17% of the metabolic clearance after subtotal gastrectomy. In a woman with radiological giant rugae of the stomach, histamine-fast achlorhydria and hypoproteinemia, the gastric clearance of serum albumin was 5.6 ml/hr. The gastric clearance of serum albumin as determined by the single radial immunodiffusion method was similar to the one measured with ^{131}I-serum albumin. In 16 normal subjects and 5 patients with duodenal ulcer, the correlation coefficient between both methods applied simultaneously was 0.7896 for 43 basal samples and 0.5320 for 40 samples after stimulation. The correlation between both methods is considerably better for 12 one-hour samples of gastric juice from 2 pernicious anemia patients (0.9827). These results suggest: (1) that albumin is not secreted by the chief and parietal cells of the gastric mucosa but probably passes through the gastric wall between the mucosal cells, perhaps during the exfoliation of the surface epithelial cells; and (2) that the stomach is one of the sites of serum albumin breakdown, a fact that supports the view that the gastrointestinal tract plays a major role in the catabolism of serum albumin.

5481 ACQUISITION OF A PYLORIC SEPTUM OR PYLORIC DUODENAL FISTULA. *(E.)* Drapkin, R. L.; Otsuka, A. L.; Castellanos, H. L.; El Hindi, S.; Nowicka, H.; Levitan, R. (VA West Side Hosp., Chicago, Ill.). *Gastroenterology* 66(4):1234-1236, 1974.

The formation of a gastroduodenal fistula, an unusual complication of peptic ulcer, is reported here. A patient with active upper gastrointestinal hemorrhage and previous radiological evidence of duodenal deformity, was discovered to have a gastric ulcer. Nineteen days later, a pyloric septum was observed gastroscopically in the same area. The radiological examinations of the upper gastrointestinal tract were consistent with these endoscopic observations, and a prepyloric mucosal septum was found during surgery which was necessary because of recurrent hemorrhage. The formation of this prepyloric septum, an acquired lesion, in the patient appears to be the result of peptic ulcer with the formation of a fistulous tract connecting the pylorus to the duodenum.

5482 ANTRAL-GASTRIN-CELL HYPERPLASIA IN PEPTIC-ULCER DISEASE. *(E.)* Ganguli, P. C.; Polak, J. M.; Pearse, A. G. E.; Elder, J. B.; Hegarty, M. (Royal Infirm., Manchester, England). *Lancet* (7858):583-586, 1974.

Thirteen male patients with significant peptic ulcer disease were studied, including 2 with duodenal ulcer and 11 who developed recurrent ulceration after gastric surgery for duodenal ulcers. The average time to recurrence after surgery was 3.1 yr. Of the 11 patients, 10 had undergone truncal vagotomy and drainage and 1 had vagotomy and partial gastrectomy. Plasma gastrin was measured in each patient before and after meat-extract ('Oxo') test meal. In 6 patients (group A), the fasting plasma-gastrin was 497 pg/ml and in the other 7 (group B) it was 185 pg/ml. Peak gastrin concentrations after Oxo were 1304 and 405 pg/ml, resp. The integrated gastrin response was 2490 and 601 pg, resp. None of the patients had a pancreatic tumor at laparotomy. Each patient underwent a hemigastrectomy. A specific immunofluorescence technique was used to examine the gastrin (G) cells in the resected antrum. All patients with hypergastrinemia (group A) had numerous G cells in their antra, whereas group B patients had significantly fewer G cells. These differences in plasma-gastrin response and in the appearance of the antrum under immunofluorescence were striking and suggested that antral-G-cell hyperplasia may be a separate clinical entity.

5483 BACTERIOLOGY OF THE STOMACH IMMEDIATELY FOLLOWING VAGOTOMY: THE GROWTH OF Candida albicans.

(E.) Brooks, J. R.; Smith, H. F.; Pease, Jr., F. B. (Harvard Med. Sch., Boston, Mass.). *Ann. Surg.* 179(6):859-862, 1974.

A short term investigation of the gastric microorganism flora in 71 patients (44 male and 27 female) included an analysis of the gastric cultures taken from 63 patients during surgery and from 50 patients postoperatively. Although the intraoperative cultures were sterile in 43 of the cases (69%), the specific microorganisms encountered in 20 of the other cultures included: Alpha-hemolytic *Streptococcus* (18 out of 20 cases), *Staphylococcus epidermidis* (11 cases); *Candida* species (5 cases); *D. pneumoniae* (3 cases); *Neisseria* species (3 cases); *Lactobacillus* (2 cases); and *Citrobacter, Herellea vaginicola, Micoplasma*, *Micrococcus, Pseudomonas aeruginosa,* and *Staphylococcus aureus* (1 case each). In the postoperative period, 48 of the 50 patients cultured showed growth of organisms (96%). The specific microorganisms found in these cultures included: *Candida* species (39 cases); diphtheroids (16 cases); *Lactobacillus* (12 cases); Alpha-hemolytic *Streptococcus* (12 cases); *Staphylococcus epidermidis* (10 cases); *Mycoplasma* (8 cases); *Klebsiella* group (6 cases); *D. pneumoniae* (5 cases); *Escherichia coli* (4 cases); *Pseudomonas aeruginosa* (4 cases); *Neisseria* species (3 cases); *Citrobacter* (3 cases); Beta-hemolytic *Streptococcus* (3 cases); and *Micrococcus* (1 case). All patients with positive cultures intraoperatively had positive cultures postoperatively, but the variety and number of organisms increased. The elevation in the pH level over 3.0 for vagotomized patients correlates well with the bacterial proliferation noted within the stomach in the postoperative state. The presence of *Candida albicans* in a very large percentage of the stomachs of post-vagotomy patients is a new finding. Several of the patients had *C. albicans* organisms in the stools, but there was no correlation between this finding and the transient diarrhea that occurs in some 10% of patients following vagotomy. In none of these cases did systemic candidiasis occur. The experience with oral mycostatin therapy in several patients who had diarrhea and gastric candidiasis was inconclusive, with some patients improving, others not.

5484 EVALUATION OF COLLOIDAL BISMUTH (DE-NOL) IN THE TREATMENT OF DUODENAL ULCER EMPLOYING ENDOSCOPIC SELECTION AND FOLLOW UP.

(E.) Salmon, P. R.; Brown, P.; Williams, R.; Read, A. E. (Dept. Med., Bristol Roy. Infirm., England). *Gut* 15(3):189-193, 1974.

A double-blind, placebo-controlled trial of colloidal bismuth (De-Nol) (10 ml diluted with 15 ml water 6 times daily) was performed on 20 patients with active duodenal ulceration (10 patients receiving placebos and 10 the active medication) by employing endoscopic selection and follow up after a treatment period of 28 days. All patients admitted to the trial presented with dyspepsia of varying severity and duration. There was no significant difference in improvement of these symptoms between the recipients of placebos and bismuth. Endoscopically, a statistically significant difference was seen in the number of patients showing ulcer healing at 28-32 days in the bismuth group (9 out of 10) compared with the placebo group (3 out of 10). There were 7 completely healed ulcers in the treated group and only 1 in the placebo group. In a preliminary pilot study, no change in acid-base balance (arterial pH, $PaCo_2$, base excess, plasma bicarbonate, standard bicarbonate) was found in 5 healthy subjects (age range 25-35) treated with 50 ml colloidal bismuth compound (De-Nol) daily for 7 days. Similarly here, no adverse side effects were noted by any patients. Blackening of the stools was noted by some subjects and a slight ammoniacal odor by others, but neither was considered sufficiently unpleasant to prevent any subject from taking the prescribed dose. The results indicate that colloidal bismuth compound (De-Nol) increases the rate of healing of duodenal ulcers over a short follow-up period.

5485 THE DUMPING SYNDROME AND THE HYDROGEN ION CONCENTRATION OF THE GASTRIC CONTENTS.

(E.) Thomson, J. P. S.; Russell, R. C. G.; Hobsley, M.; Le Quesne, L. P. (Middlesex Hosp. Med. Sch., London, England). *Gut* 15(3):200-206, 1974.

The dumping provocation test (p.o. administration of 200 ml 50% dextrose) was performed on 40 patients (34 men and 6 women; average age 44 yr) who had undergone surgery for duodenal ulcers. Surgery consisted of vagotomy (truncal in 18, selective in 22) combined with a drainage procedure (Heineke-Mikulicz pyloroplasty in 18, gastroduodenostomy in 12, gastrojejunostomy in 10). Of the 27 examined shortly after surgery, 15 were studied before surgery. Any fall in plasma volume during the dumping provocation test was assessed by serial measurement of the hematocrit, and an insulin gastric secretion test was performed on each patient. Dumping symptoms varying in severity developed after meals in 20 operated patients. In all 20 patients, dumping symptoms were also produced by the dumping provocation test, which caused similar symptoms in 3 other patients who had no evidence of dumping after meals. There were no significant differences in the occurrence of dumping symptoms between patients who had truncal vagotomy and selective vagotomy, between patients with the 3 different types of drainage procedure, and between those patients who were studied after 6 months. After surgery there was a correlation between the occurrence of dumping symptoms following oral hypertonic glucose and the H^+ concentration of the gastric contents, both in the basal state and after insulin hypoglycemia. The lower the basal H^+ concentration and the lower the peak H^+ concentration after insulin hypoglycemia, the greater was the tendency to develop dumping symptoms. In patients with dumping syndrome, there was no significant difference between the basal and peak H^+ concentrations, while in asymptomatic patients the peak H^+ concentration was significantly higher. These findings, together with an analysis of the results with regard to Hollander's criteria, suggest that dumping symptoms are most likely to develop in patients with complete vagal innervation of the stomach. However, since Hollander's criteria do not take into account factors such as pyloric loss and duodenal reflux, which affect the H^+ concentration

LIBRARY [illegible]

of the gastric juice, it is not possible to make a definite statement concerning the relation between the occurrence of dumping symptoms and the completeness of vagus nerve section. The occurrence of dumping symptoms after partial gastrectomy or simple gastrojejunostomy might be explained by more rapid gastric emptying resulting from a decreased gastric H^+ concentration or by decreases in gastric H^+ concentration resulting from the removal of the greater part of the parietal cell mass or reflux of alkaline intestinal contents into the stomach.

5486 KALLIKREIN-KININ SYSTEM IN POSTGASTRECTOMY DUMPING SYNDROME. *(E.)* Wong, P. Y. Talamo, R. C.; Babior, B. M.; Raymond, G. G.; Colman, R. W. (Boston City Hosp., Mass.). *Ann. Int. Med.* 80(5):577-581, 1974.

The kallikrein-kinin system was studied in 10 postgastrectomy patients, 5 with the dumping syndrome and 5 without symptoms. After drinking 220 ml of 45% glucose (test meal) none of the asymptomatic patients developed symptoms of the dumping syndrome, elevated levels of bradykinin, or prekallikrein activation; the mean blood pressure fall was not significant. The symptomatic group had headaches, lightheadedness, diarrhea, and a significantly decreased mean blood pressure of 19.4%. A rise in plasma bradykinin levels to above normal occurred in all patients. Two had activation of plasma kallikrein, manifested by a drop in prekallikrein and complete disappearance of kallikrein inhibitor; 1 of these 2 also had increased free kallikrein, showed by kinin release from kininogen. The mechanism of kinin release in the other 3 patients was unknown. These findings suggest that kinins may mediate some features of the dumping syndrome. In some patients, kinin release seemed to result from the formation of plasma kallikrein. In others, the exact mechanism of kinin release is unclear.

5487 LATE RESULTS OF BILATERAL SELECTIVE VAGOTOMY AND PYLOROPLASTY FOR DUODENAL ULCER: 5-9 YEAR FOLLOW-UP. *(E.)* DeMiguel, J. *Br. J. Surg.* 61(4):264-269, 1974.

Through a period of 4 yr, bilateral selective vagotomy and pyloroplasty were performed for duodenal ulcer on 135 patients (119 men and 16 women) without postoperative mortality. Elective operations were for intractable pain (116 patients) and pyloric stenosis (11 patients); emergency operations were for acute perforation (6 patients) and active massive hemorrhage (2 patients). Two unrelated deaths (coronary occlusion and carcinoma of the colon) occurred during the period of the survey and 2 other patients were lost to follow-up. The remaining 131 patients were followed up for a minimum of 5 yr and a maximum of 9 yr. The most frequent symptoms were milk intolerance (30 patients), epigastric fullness (29 patients), early dumping (19 patients) and mild diarrhea (24 patients). Only 1 case of moderate diarrhea was observed, and none of severe diarrhea. Food vomiting occurred in 2 patients; bile vomiting in 4; and hypoglycemia-like attacks in 3 patients. Recurrent duodenal ulcer was proved in 4.6% and highly suspected in 1.5%. Gastric ulcer was proved in 3.1%. Approximately 91% of the patients were classed as having a satisfactory result and 9% were unsatisfactory. Bilateral selective vagotomy is clearly effective in controlling ulcer diathesis in the long term, and it seems to lessen some of the side-effects of gastric surgery. For these reasons, consideration should be given to its use in the surgical treatment of duodenal ulcer.

5488 GASTRIC ACID RESPONSE TO SHAM FEEDING BEFORE AND AFTER RESECTION OF ANTRUM AND DUODENAL BULB IN DUODENAL ULCER PATIENTS. *(E.)* Knutson, U.; Olbe, L. (Sahlgrenska Hosp., Goteborg, Sweden). *Scand. J. Gastroenterol.* 9(2):191-201, 1974.

The gastric acid response to physiological vagal stimulation by 15-min sham feeding was studied in 25 duodenal ulcer patients with intact antrum and in 15 duodenal ulcer patients after resection of the antrum and duodenal bulb. In 5 patients sham fed before and after the resection, the peak acid response to sham feeding was reduced by 61% following resection. The antrum-bulb resection reduced by 47% the maximal acid response to betazole (2 mg/kg s.c.) or pentagastrin (90 μg/hr for 45 min. i.v., followed by 300 μg/hr for 45-60 min). In the nonresected patients, the peak acid response to sham feeding amounted to 53% of the maximal acid response to betazole or pentagastrin, while the postresection relation was 33%. The results indicate that the vagal release of gastrin from the antrum-bulb region contributes to, but is not essential for, the gastric acid response to physiological vagal activation in the ulcer patients. Furthermore, the marked reduction in the vagally activated secretion of acid following antrum-bulb resection in man seems to be due primarily to a general and irreversible decline in the acid secretory capacity and only to a minor extent to the elimination of the acid stimulatory effect of vagally released gastrin from the antrum-bulb region.

5489 HIGHLY SELECTIVE VAGOTOMY AND DRAINAGE FOR DUODENAL ULCER STENOSIS. *(E.)* El-Katib, Y.; Mashhoor, N. (Fac. Med., Cairo Univ., Egypt). *Br. J. Surg.* 61(3):241-243, 1974.

Thirteen patients with pyloric stenosis secondary to duodenal ulceration underwent highly selective vagotomy and gastroenterostomy. All 13 patients were men aged 32 to 55 yr. Preoperative preparation consisted of gastric lavage with normal saline twice a day and correction of any electrolyte disturbances and deficiencies. A gastric vagotomy was performed but the antrum was not denervated; the anterior and posterior nerves of Latarjet were left intact. A greater curvature gastroenterostomy followed. Postoperatively, gastric aspiration was continued for up to 72 hr, with oral fluids given at 48 hr. By 10 days postoperatively, there was complete gastric evacuation of a barium meal within 4 hr in 9 cases and within 6 hr in the remaining 4 cases. Within 2 weeks all patients were discharged, none having any sour eructations or vomiting. Insulin tests administered 3 weeks postoperatively were all negative. The patients were followed up for periods of 5 to 15 months; none showed symptoms of recurrent ulceration. This surgical program should be considered in the treatment of well-prepared patients.

5490 PHARMACOLOGICAL PROTECTION AGAINST SWINE STRESS ULCER. *(E.)* Norton, L.; Mathews, D.; Avrum, L.; Eiseman, B. (Denver Gen. Hosp., Colo.) *Gastroenterology* 66(4):503-508, 1974.

The ability of cholestyramine, methysergide, and methylprednisolone to protect against stress ulceration was evaluated in a swine hemorrhagic shock model. Twelve control piglets developed gastric ulcers within 48 hr of hemorrhagic shock. Cholestyramine (50 mg/kg in a liquid meal) administered 12 hr before hemorrhage prevented ulceration in 8 of 9 animals (89%), providing additional evidence that swine stress ulceration depends upon the reflux of bile into the stomach. When cholestyramine administration was delayed for 1 hr, only 2 of 5 swine were protected, suggesting that bile damage to the mucosa occurs rapdily. Prefeeding with methysergide (5 mg/kg), a serotonin antagonist, protected 2 of 4 piglets. Giving methysergide i.v. during shock afforded no protection to 4 other animals. Methylprednisolone given in high doses (15 mg/kg) i.v. to 5 piglets early in shock prevented ulceration in all cases. Delaying administration by 1 hr resulted in ulceration in 5 of 5 animals. The mechanism of methylprednisolone protection was not studied, but the results are consistent with the hypothesis that steroids stabilize lysosomal membranes. On the basis of results in the swine model, cholestyramine and methylprednisolone might be considered for clinical trial as pharmacological prophylaxis against stress ulceration. Their success appears to depend on administration soon after the stressful event.

5491 SERUM CALCIUM, SERUM GASTRIN, AND GASTRIC ACID SECRETION BEFORE AND AFTER PARATHYROIDECTOMY FOR HYPERPARATHYROIDISM. *(E.)* Stremple, J. F.; Watson, C. G. (Univ. of Pittsburgh, Pa.). *Surgery* 75(6):841-852, 1974.

Serum calcium, serum gastrin, and gastric acid secretion measured in 19 patients (10 women, 9 men) with primary hyperparathyroidism before and after parathyroidectomy. Fourteen patients had neither gastric nor duodenal ulcers, and 3 of these 14 had primary parathyroid hyperplasia rather than adenoma. Other conditions present with the hyperparathyroidism were: Duodenal ulcer (3); both gastric and duodenal ulcers (1); elevated basal serum gastrin (2); and markedly elevated serum gastrin level within the Zollinger-Ellison range, but no basal acid or ulcer (1). In the hyperparathyroid patients, results were as follows: (1) serum parathormone level (normal mean 4.0 ng/ml): elevated 50% above normal in patients with and without ulcers preoperatively but dropped in both to below normal after surgery; (2) serum calcium (normal mean 10 mg/100 ml): about 1/5 elevated pre- and about 1/5 reduced post-operatively in both ulcerated and non-ulcerated patients; and (3) basal serum gastrin (normal mean 36 pg/ml): elevated about 4-fold in patients without ulcer but only 2-fold in ulcer patients before surgery; after operation non-ulcerated as well as ulcerated patients showed gastrin levels about 3 times normal. In patients with duodenal ulcer but without hyperparathyroidism, the level of gastrin was about 50% above normal. The serum gastrin did not decrease postoperatively in patients with parathyroid hyperplasia. In the one hyperparathyroid patient with gastrin levels in the Zollinger-Ellison range, the mean systemic serum gastrin before parathyroidectomy was 2,035 pg/ml; the parathyroid adenoma tissue gastrin content was 16,216 pg/mg tissue; and the postoperative mean systemic serum gastrin level were 350 pg/ml. The high tissue gastrin content in the parathyroid adenoma removed from this patient, as determined by radioimmunoassay and immunofluorescence, and the decrease in serial serum gastrin measurements after its removal demonstrated that this parathyroid adenoma was also the source of gastrin: it was a parathyroid gastrinoma. In non-ulcerated patients with hyperparathyroidism, there were low basal acid levels both before and after parathyroidectomy but in those with duodenal ulcer, levels were 6 x normal pre- and 3 x normal postoperatively. The results confirm the previously reported increase in serum gastrin in patients with hyperparathyroidism without ulcer and the decrease in serum gastrin after parathyroidectomy. These findings indicate that gastrin can be added to the list of hormones secreted by a parathyroid adenoma.

5492 MECHANISM OF STRESS ULCER. IV. INFLUENCE OF FASTING ON THE TOLERANCE OF GASTRIC MUCOSAL ENERGY METABOLISM TO ISCHEMIA AND ON THE INCIDENCE OF STRESS ULCERATION. *(E.)* Menguy, R.; Masters, Y. F. (Univ. Rochester Sch. Med., N.Y.). *Gastroenterology* 66(6):1177-1186, 1974.

Hemorrhagic shock of 15 min duration in rabbits caused a severe gastric mucosal energy deficit due to shock-induced mucosal ischemia characterized by marked reduction of ATP and also the total of ATP + ADP + AMP. The deficit was more severe in the fundus and corpus than in the antrum, and was significantly more severe in all three regions in fasted as opposed to nonfasted animals. Measurement of glucose-6-phosphate levels indicated some acceleration of glycolysis in the antrum under fasted conditions. Feeding, supplemented by a carbohydrate load, rendered the gastric mucosa less vulnerable to stress ulceration. None of the nonfasted rabbits had grossly visible mucosal erosions when examined 3 hr after shock, but all but 1 of the fasted rabbits had erosive gastritis of varying severity. The hyperglycemia associated with hemorrhagic shock was absent in fasted animals, probably as a result of the rapid depletion of inadequate glucose reserves thereby reducing the amount available for anaerobic glycolysis. Such a reduced anaerobic glycolytic flux, as shown by blood lactate levels in nonfasted rabbits, would cause a further decline in the energyroducing capacity of ischemic tissues. Results uggest that the animal's state of nutrition is another odifier of the phenomenon of stress ulceration and hould be considered in any experimental study of his problem.

5528 THE ROLES OF INTRALUMINAL CHYME AND VASOMOTOR RESPONSE IN THE PATHOGENESIS OF NON-OCCLUSIVE INTESTINAL INFARCTS. *(E.)* Kwan, A.; Chiu, C. J.; Mersereau, W.; Hinchey, E. J. (McGill Gen. Hosp., Montreal, Canada). *Ann. Surg.* 179(6):877-882, 1974.

The role of intraluminal chyme and the splanchnic vasomotor reaction in the pathogenesis of non-occlusive intestinal infarcts was studied in 5 mongrel dogs, in which 3 types of intestinal loops were created: (1) cervical loop, a heterotopic autotransplant of a segment of intestine, with no chyme, and disconnected from splanchnic innervation: (2) Thiry-Vella loop, simultaneously constructed in the abdomen also devoid of intraluminal chyme, but still innervated; and (3) intestine-in-continuity, with both splanchnic innervation and intraluminal chyme. Hemorrhagic shock was then induced and the morphological response of these types of ntestine examined. Mucosal hemorrhages were ob-erved in both the Thiry-Vella loops and the in-estine-in-continuity, and microscopy of repre-entative sections of each loop of intestine also howed severe damage to the intestinal mucosa. he microvasculature of the mucosa revealed the bsence or minimal presence of previously i.v. dministered colloidal carbon particles in the vas-ular endothelium of the cervical loops, but both ypes of intestinal loops retained carbon parti-les on the vascular wall, suggesting damage to the ndothelium. These results indicate that in non-cclusive hemorrhagic infarction of the intestinal ucosa, the peculiar splanchnic vasomotor response lays a dominant role. Various therapeutic modali-ies may be useful in the treatment and prevention f the non-occlusive intestinal infarcts, including reatment of the low flow state itself, with volume xpansion and the administration of cardiac ino-ropic agents. Adrenergic blocking agents may be sed to alleviate splanchnic vasoconstriction and he instillation of enzyme inhibitors and antibi-tics may decrease the effects of intraluminal di-estive enzymes and toxins.

529 DUODENITIS. *(E.)* Gregg, J. A.; Garabedian, M. (Lahey Clin. Fdn., Boston, lass). *Am. J. Gastroenterol.* 61(3):177-184, 1974.

ndoscopic evidence of duodenitis was encountered n 44 of 145 consecutive patients examined mostly or esophageal or gastric problems; 20% were referred or indeterminate upper abdominal pain. Visually, uodenitis was associated with patchy areas of ery-hema and edema and, in a few instances, mucosal emorrhage. In 31 patients, these findings were een without duodenal ulceration while in 13 pa-ients duodenitis was associated with duodenal ulcer lthough the duodenitis was remote from the area of lceration in 8 of these patients. In most cases uodenitis occurred as a solitary finding or in asso-iation with gastritis (2 patients), gastric ulcer r gastric erosions or both (4 patients), or eso-hagitis (2 patients). Histologically the lesion onsisted of variable degrees of infiltration with ound cells. The presence or absence of inflamma-ory disease in the bulb, as determined histologic-lly, correlated well with the endoscopic findings. ther than deformity of the bulb, no radiological indings suggested the presence of duodenitis. uodenitis had healed completely in 3 of 5 patients ho were examined endoscopically after an appropri-te period on an ulcer diet, milk, and antacids. t was not possible to determine whether duodenitis *er se* produced any symptoms in this series.

530 AN ANIMAL MODEL FOR THE STUDY OF SMALL-BOWEL TUMORS. *(E.)* Coop, K. L.; harp, J. G.; Osborne, J. W.; Zimmerman, G. R. (Coll. ed., Univ. Iowa, Iowa City). *Cancer Res.* 4(6):1487-1494, 1974.

o facilitate study of tumors of the human gastro-ntestinal tract, a possible animal model for this urpose was investigated. Since chemical carcino-ens often involve many problems, tumors here were induced in male Holtzman rats by X-irradiation of only the hypoxic, temporarily exteriorized ileum and jejunum. Following an exposure to 200 r, 56% of the rats developed adenocarcinoma somewhere in the irradiated segment. The majority of rats with intestinal tumors could be identified in the terminal phase of illness by their hunched posture and inability to perform normal body movements. Macroscopic intestinal tumors were observed at autopsy in 58 of the 103 rats. Pathological features observed in the remaining 45 rats included pneumonia, intestinal vasculitis, and features characteristic of the gastrointestinal radiation syndrome. Macroscopic metastases were not observed outside the small intestine; however, metastases or direct extensions were seen microscopically in the mesentery, pancreas, and abdominal wall. A hypochromic microcytic anemia was associated with the tumors and appeared to be the result of blood loss from the tumors into the intestinal lumen. Other pathological features associated with these tumors were weight loss, diarrhea, obstruction of the small bowel, and intestinal perforation and hemorrhage. These features are similar to those described in the literature for malignant tumors of the small intestine in humans. This animal model, therefore, would appear to be potentially useful for studies relating to humans with small-bowel neoplasms.

5531 INTRAMURAL DUODENAL HEMATOMA. *(E.)* Fullen, W. D.; Selle, J. G.; Whitely, D. H.; Martin, L. W.; Altemeier, W. A. (Univ. Cincinnati Med. Ctr., Ohio). *Ann. Surg.* 179(5):549-556, 1974.

Fourteen patients (8 males and 6 females, aged 4-68 yr) treated for intramural duodenal hematoma were studied. Contrast radiographic evidence was the basis for diagnosis in 13 cases, and 1 case was discovered at laparotomy. The treatment in 11 cases was nonoperative, consisting of restriction of oral intake, nasogastric suction when indicated, and i.v. infusion of fluids and electrolytes; all 11 patients survived without complication. The other 3 patients were operated on, 1 for an incorrect diagnosis of acute appendicitis and 2 with a correct preoperative diagnosis of intramural duodenal hematoma. All of these patients survived, although 1 pediatric patient required reoperation one day postoperatively. The symptom complex in this series of patients was generally one of mild to moderate abdominal pain beginning after blunt trauma to the abdomen. Thus, diagnostic consideration of intramural duodenal hematoma should not depend on the totally symptom-free interval previously described as typical of the lesion. The physical findings consisted of abdominal tenderness in the epigastrium or upper quadrant with frequent voluntary guarding. Blood loss was not great and hyperamylasemia was encountered in only a small number of patients. Conservative therapy is recommended for patients with a secure diagnosis of intramural duodenal hematoma in whom no additional injuries requiring laparotomy are identifiable.

5551 STUDIES ON THE NATURE AND SIGNIFICANCE OF CONNECTIVE TISSUE ANTIBODIES IN ADULT COELIAC DISEASE AND CROHN'S DISEASE. *(E.)* Magalhaes, A. F. N.; Peters, T. J.; Doe, W. F. (Roy. Postgrad.

led. Sch., London, England). *Gut* 15(4):284-288, 974.

his study was designed to determine the significance f the presence of connective tissue antibodies in dult celiac disease, their immunoglobulin class, nd their relationship to gluten withdrawal from the iet. Ninety-two patients with this disease (70 emales and 22 males, 12-65 yr old) were investigated; 4 received a normal diet while 73 were on a gluten- ree diet for at least 3 months. Similarly tested ere 20 patients with Crohn's disease and 89 control atients. Serum positive for the connective tissue ntibodies was found in 36 (39%) of the 92 patients ith adult celiac disease, and these were classified s IgA (13), IgG (16), and both (7). The antibodies ere also found in 5 out of the 20 Crohn's disease era; all were IgG class. Positive sera (both IgG) ere found in only 2 of 89 controls: one had chronic iver disease and the other, chronic lymphatic eukemia. Of 44 patients on a normal diet, 25 58%) had positive sera (IgA 11; IgG 7; and both) while the 73 gluten-free diet patients showed positive sera in 17 (23%) of the cases (IgA 3; gG 13; and both 1), a striking reduction in IgA. ejunal fluid collected from 15 celiac patients to nvestigate the site of antibody secretion showed no ntibody activity, including 7 patients whose sera ere positive. Connective tissue antibody activity as not absorbed by fractions of gluten. In addition, reparations of human reticulin and glomerular base- ent membrane as well as elastin and collagen failed o absorb connective tissue antibody. While the na- ure of the antigens against which these antibodies re directed remains obscure, it seems likely that hey result from a combination of tissue damage and efective antigen handling and are unlikely to be of athogenetic significance.

552 TRANSIENT KWASHIORKOR: A CAUSE OF FATTY LIVER FOLLOWING SMALL BOWEL BYPASS. *(E.)*

hite, J. J.; Moxley, R. T.; Pozefsky, T.; Lockwood, . H. (Johns Hopkins Univ. Sch. Med., Baltimore, d.). *Surgery* 75(6):829-840, 1974.

hanges in protein nutrition were compared with al- erations in hepatic morphology and function in 18 atients (22 to 41 yr) undergoing small bowel bypass or morbid obesity. Weight loss was considered atisfactory but was accompanied by intestinal malabsorption. Fecal fat excretion averaged 2.7 g/day reoperatively but increased significantly after urgery. Decreases in serum cholesterol from 189 g% to 130-140 mg%, and in D-xylose excretion from .18 g/5 hr to 2.4 g/5 hr were noted. Moderate o marked hepatic fat accumulation occurred during he periods of intense weight loss with return to reoperative levels after weight stability was ttained. Amino acid profiles showed significant epressions in 6 of the 7 essential amino acids with nly methionine unchanged. Among the 12 nonessential amino acids assayed, significant reductions occurred in 6; proline, taurine, and histidine were unchanged; and serine and glycine levels were significantly elevated. Reduced absorption of lysine, leucine, and glycine were observed in patients who had achieved weight stability and reduction in fatty metamorphosis of the liver toward normal levels. These studies demonstrate that a state of protein malnutrition develops during the period of intense weight loss following jejunoileal bypass and that protein nutrition returns toward normal levels coincident with attainment of weight stability. Significant fatty infiltration of the liver also develops during intense weight loss. The morphologic similarity between these changes and those noted in the livers of patients with kwashiorkor and in those of laboratory animals made protein-deficient suggests that their etiology may be similar.

5553 INTESTINAL DIPEPTIDASES IN PRIMARY PROTEIN MALNUTRITION. *(E.)*

Hazuria, R. S.; Sarin, G. S.; Srivastava, P. N.; Misra, R. C.; Bhatt, I. N.; Chuttani, H. K. (Maulana Azad Med. Coll., New Delhi, India). *Am. J. Clin. Nutr.* 27(7):760-763, 1974.

Intestinal dipeptidase activities were studied in 20 normal control subjects and in 9 patients with primary protein malnutrition. This study in India revealed that the controls had low levels as compared with American and European figures. Although the glycyl-L-leucine and glycyl-L-valine dipeptidase activity levels of the patients were significantly lower (58.8 and 43.9 U/mg N/min, resp.) than those of the control subjects (124.9 and 88.9 U/mg N/min, resp.), no gross damage to their intestinal mucosa was observed. Possibly, early, minor morphological changes in the brush border were missed by the light microscope but were severe enough to affect the enzyme levels. It is postulated that the effects of protein deficiency are increased because the enzymes, present in insufficient amounts due initially to protein malnutrition, are unable to act on the low levels of protein available in the gastrointestinal tract, thus creating and propagating a vicious cycle.

5554 BILE SALT METABOLISM IN TROPICAL SPRUE. *(E.)*

Bevan, G.; Engert, R.; Klipstein, F. A.; Maldonado, N.; Rubulis, A.; Turner, M. D. (Univ. Rochester Sch. Med., Dent., N.Y.). *Gut* 15(4):254-259, 1974.

To assess the importance of bile salts in the pathogenesis of steatorrhea in tropical sprue, mean and peak jejunal bile salt concentrations measured during digestion of a standard fat meal in 6 Puerto Rican patients with the untreated disease, all of whom had steatorrhea, was found to be significantly lower (mean 2.4 mM/liter; peak 5.4 mM/liter) than in 6 asymptomatic subjects (mean 11.9 mM/liter; peak 21.4 mM/liter) from the same population who had normal fat absorption and no steatorrhea. Bile salt pool size and turnover time did not significantly differ in the 2 groups. Other laboratory investigations included bone marrow and jejunal morphology examinations, as well as measurements of hemoglobin, serum folate, serum vitamin B_{12}, ^{57}Co-vitamin B_{12} absorption, xylose absorption (urine excretion and serum peak), and fecal fat. It is suggested that bile salt concentrations may be reduced in the proximal small intestine of patients with tropical sprue as a result of excessive dilution of intestinal fluid since patients with this disease have been found to be in an active secretory state for water and electrolytes. The finding of low bile salt concentrations in 2 asymptomatic subjects indicates that bile salt lack alone may not be sufficient to produce steatorrhea.

5555 INTESTINAL EXFOLIATED CELLS IN INFANTS: A SYSTEM FOR STUDY OF MICROVILLOUS PARTICLES. *(E.)* Torres-Pinedo, R.; Rivera, C.; Garcia-Castineiras, S. (Univ. Puerto Rico Sch. Med., San Juan). *Gastroenterology* 66(6):1154-1160, 1974.

Products of jejunal mucosal exfoliation in 8 infants (3-5 months old) were collected from the intestinal lumen by intestinal perfusion. The brush border materials collected in the perfusion solutions were separated into 3 fractions by differential centrifugation. The first fraction contained large brush border fragments and intact brush borders, including those still attached to degenerating cells. The second fraction was composed mainly of split microvilli, while the third fraction contained amorphous residues of the microvilli. Since exfoliated jejunal enterocytes are rapidly digested and autolyzed in the intestinal lumen, the collection of desquamated cells was attempted here by intestinal perfusion of infants who had recovered from postenteritic lactose intolerance but who were healthy and growing normally on a lactose-free diet. The specific activities of sucrase in the perfusion solution and in the microvilli (second) fractions were comparatively not much lower than those reported in mucosal biopsies of infants and children and in highly purified microvillous membranes from human intestine. These findings indicate that sucrase is retained to a certain extent on the microvillous surface during cell desquamation and breakage. The relative proportions of microvillous and nonmicrovillous protein in the 3 fractions were assessed by using sucrase as a tracer of the microvillous membrane. The enzyme was more or less evenly distributed among the 3 fractions, but its specific activity was 5 times higher in the microvillous fraction (0.52 μM/min/mg of protein).

LARGE INTESTINE

5565 MUCUS-SECRETING COLONIC CARCINOID TUMORS: LIGHT- AND ELECTRON-MICROSCOPIC STUDY OF THREE CASES. *(E.)* Hernandez, F. J.; Fernandez, B. B. (Lutheran Gen. Hosp., Park Ridge, Ill.). *Dis. Colon Rectum* 17(3):387-396, 1974.

Case histories of 3 patients (2 women and 1 man, 60-80 yr old) with carcinoid tumors that showed mucus secretion and had the typical histologic features of carcinoid tumors are presented. One patient died 2 yr after surgery. Two of the tumors (rectal carcinoids) were argentaffin-positive; the other, an appendiceal tumor, was argentaffin-negative but argentaffin granules were demonstrated in the cytoplasm of the tumor cells at the ultrastructural level. Examination with electron microscopy revealed PAS-positive droplets in 2 specimens which corresponded at the ultrastructural level to numerous apical and perinuclear vacuoles that compressed the enterochromaffin granules toward the periphery of the cytoplasm. In some of the cells the vacuoles and argentaffin granules were intimately related to the Golgi apparatus. The argentaffin granules were found mostly in subnuclear locations and, except for the coexistence with secretion vacuoles in the cytoplasm of the tumor cells, no definite morphologic relationship between these 2 cell products could be established. Nests of tumor cells with numerous argentaffin granules and no evidence of intracytoplasmic vacuoles were encountered in some areas. The specimen from the third patient contained nests of carcinoid cells with a smaller number of argentaffin granules in the cytoplasm and with clusters of small vacuoles in one pole of the cells, usually opposite the aggregates of enterochromaffin granules. Scattered intracytoplasmic mucin droplets shown by light microscopy to be associated with the argentaffin granules corresponded at the ultrastructural level to large vacuoles limited by a single membrane. Mucus secretion in carcinoid tumors does not bear any relation to the extent of malignancy; and, mucus-secreting adenocarcinomas evolving from carcinoid tumors behave like other colonic adenocarcinomas.

5566 IMMUNOLOGICAL DETECTION OF ANTIGEN(S) ASSOCIATED WITH RAT COLON CARCINOMA. *(E.)* Garmaise, A. B. K.; Rogers, A. E.; Newberne, P. M.; Saravis, C. A.; Kupchik, H. Z.; Zamcheck, N. (Massachusetts Inst. Technol., Cambridge). *Nature* 248(5450):706-707, 1974.

The rat with adenocarcinoma of the colon, induced by 1,2-dimethylhydrazine, is presented as a useful animal model for the study of human colon carcinoma. Twenty-eight male Sprague-Dawley rats (4 weeks old) were fed a semisynthetic diet for 3 months, given 10 weekly intragastric doses of 1,2-dimethylhydrazine (30 mg/kg), and killed 6 to 8 months later when tumors causing bleeding intussusception or obstruction developed in the intestine. At autopsy, colon tumors 3 cm or greater in diameter as well as sections of normal colon were frozen in liquid nitrogen. Pooled tumors (4.2 g) were minced and homogenized, centrifuged, and dialysed. Antibodies to the tumor macromolecules were produced in New Zealand adult rabbits and they were bled 7 days after the last injection, injected again, and then bled repeatedly for several weeks. Heterologous antibodies were removed from the antisera by absorbing with extracts of normal rat colon and affinity chromatography beads. Absorbed antisera to rat colon tumors (10 μliters) were reacted by the Ouchterlony technique. Counterimmunoelectrophoresis was performed in which macromolecules from the colon tumors and normal colon were electrophoretically transported to the absorbed tumor antibodies. When seven 2-fold serial dilutions of colon tumor extract and of normal colon extract were reacted with a constant concentration of antibody to rat colon tumors, reactions were obtained with the tumor extract at all dilutions, but no reactions were obtained with dilutions of the normal colon extracts. Preliminary work indicates that the absorbed antisera reacted with extracts made from 40 fetal Sprague-Dawley rats (14th day of gestation). Counterimmunoelectrophoresis indicated a strong reaction between fetal extract components and the tumor antibodies. Results showed that the tumor antibodies did not cross-react with human carcinoembryonic antigen, and rat tumor antigen did not react with anti-carcinoembryonic antigen antisera.

5567 TREATMENT OF SCHISTOSOMAL POLYPOSIS OF THE COLON WITH NIRIDAZOLE (AMBILHAR). *(E.)* Farid, Z.; El Masry, N. A.; Young, S. W.; Bassily, S.; Sparks, H. A.; Hassan, A. (Abbassia Fever Hosp., Cairo, Egypt). *J. Trop. Med. Hyg.* 77(3):65-67, 1974.

For schistosomal polyposis of the colon, found in 20% of Egyptian farmers with schistosomiasis and previously treated by surgery only, immediate and long-term results of another therapeutic approach with niridazole is reported. Seventeen male farmers (16 to 45 years old) with multiple schistosomal polyposis of the colon, acute bloody diarrhea, severe anemia, and hypoalbuminemia were treated with niridazole (25 mg/kg/day) p.o. for 10 days. The immediate results of treatment were excellent. Symptomatic improvement was rapid, and bloody diarrhea ceased in all patients within 1 to 2 weeks of completing treatment. The anemia and hypoalbuminemia were corrected with oral iron and a high protein diet. Three to six months after treatment, all patients had ceased to pass live *Schistosoma mansoni* eggs in their stools. Sigmoidoscopic and air contrast barium enema examinations showed marked improvement in all 17 patients. In 12, there was complete resolution of all the polyps, and in the remaining 5 patients, only a few polyps remained in the rectosigmoid colon. However, 2-3 years after treatment, only 2 patients remained uninfected, and 10 of the reinfected subjects had recurrence of active polyposis of the rectosigmoid colon with bloody diarrhea. It is suggested that all patients should be checked at 12 month intervals and treated again with niridazole if they are reinfected.

5568 INTESTINAL STREAMING PATTERNS IN CHOLERRHOEIC ENTEROPATHY AND DIVERTICULAR DISEASE. *(E.)* Findlay, J. M.; Mitchell, W. D.; Eastwood, M. A.; Anderson, A. J. B.; Smith, A. N. (Western Gen. Hosp., Edinburgh, Scotland). *Gut* 15(3):207-212, 1974.

Gastrointestinal streaming, demonstrated by differences in recovery rates of synchronously fed markers for the solid and liquid phases, was investigated in 17 patients (5 with cholerrheic enteropathy, 7 with colonic diverticulosis, and 5 with normal bowel habits) and 7 healthy volunteers. Polyethylene glycol was the liquid phase marker administered p.o. (500 mg 3 times/day), and the solid phase marker, chromium sesquioxide (Cr_2O_3), was also given p.o. (500 mg 3 times/day) synchronously with the polyethylene glycol for 1 day. The 24 hr pooled stool samples were analyzed for output of the 2 markers per 24 hr. In controls and in patients with normal bowel habits, throughput rates of polyethylene glycol and Cr_2O_3 showed no significant differences. However in subjects with cholerrheic enteropathy, the polyethylene glycol rate was 1.5 times faster than the Cr_2O_3 rate, while in the group with diverticulosis the rate was 0.75 times slower than Cr_2O_3, a significant decrease. These streaming patterns confirm current views on intestinal dysfunction in cholerrheic enteropathy and colonic diverticulosis which may reflect the effects of colonic hypersegmentation on the relative distribution of the liquid and solid phases.

5569 FAMILIAL INCIDENCE OF JUVENILE POLYPOSIS COLI. *(E.)* Gathright, J. B., Jr.; Coffer, Jr., T. W. (Ochsner Fdn. Hosp., New Orleans, LA.). *Surg. Gynecol. Obstet.* 138(2):185-188, 1974.

The familial nature of juvenile polyposis coli is discussed and certain pathologic and clinical features are presented. The onset of symptoms has been given as 3 to 6 years but is quite variable. The presenting symptom is almost always rectal bleeding. Seven of 10 members of one family had roentgenographic and histologic evidence of the disease. All 7 submitted to proctoscopic examination and, of these, 4 had polyps removed which, on histologic examination, proved to be typical juvenile polyps. Six of the patients were examined by means of barium enema, and in all of these, examinations revealed polyps above the level of sigmoidoscopic examination. At sigmoidoscopy, the polyps have a characteristic red color, contrasting sharply with the surrounding mucosa. Diagnosis can only be made histologically. Treatment includes the removal of polyps within the reach of the sigmoidoscope. Polyps prolapsing through the anus are those most often associated with bleeding. Operative intervention is rarely indicated, however; symptomatic treatment is preferable. The disease apparently has no malignant potential.

5570 DIAGNOSTIC FEATURES OF CLINDAMYCIN-ASSOCIATED PSEUDOMEMBRANOUS COLITIS. *(E.)* Tedesco, F. J.; Stanley, R. J.; Alpers, D. H. (Washington Univ. Sch. Med., St. Louis, Mo.). *N. Engl. J. Med.* 290(15):841-843, 1974.

Severe diarrhea, abdominal pain, distention, and nausea developed in 3 patients 7-10 days after institution of clindamycin (300 mg p.o. every 6-8 hr) for pneumonia, amyotrophic lateral sclerosis, and chronic renal failure. *Escherichia coli* was isolated from the stools of all 3 patients, and *Streptococcus faecalis* was present in 1 patient. When overlying mucus and cell debris was removed, proctoscopic examination revealed small (1-5 mm), raised, yellowish-white plaques on the surface of the mucosa. The mucosa was erythematous and friable. None of the smears taken from these plaque-like lesions contained staphylococcus or any enteric pathogen. Barium contrast studies of the colon showed that the entire colon was covered with many flat, plaque-like lesions ranging in size from 2-8 mm. These lesions were demonstrated very well on air contrast films. No ulcerations, "thumb printing", or larger polypoid lesions were observed. Histological examination of biopsies confirmed the diagnosis of pseudomembranous colitis. It is recommended that pseudomembranous colitis be considered in the differential diagnosis of any patient who develops a fever, ileus, or diarrhea during or soon after a course of clindamycin therapy.

5571 CAPILLARY LEAK SYNDROME WITH MASSIVE INTESTINAL EDEMA AFTER APPENDECTOMY. *(E.)* Fishbein, M. C.; State, D.; Hirose, F.; Castagna, J. (Harbor Gen. Hosp., Torrance, Ca.). *Am. J. Surg.* 127(6):740-747, 1974.

Ileus and ascites with persistent hypotension developed in a previously healthy 36-yr-old man after appendectomy for acute appendicitis. On the 5th postoperative day, laparotomy re-exploration revealed a grossly gangrenous-appearing segment of the terminal ileum and proximal colon and these were removed. Histologically, only massive acellular submucosal edema with dilation of lymphatics and a serosal hyperemia without necrosis were seen. Despite large amounts of fluid administration, central venous pressure never exceeded 20 cm H_2O, and the mean pulmonary artery pressure was always less than 15 mm Hg. Severe anasarca developed, and during the last day, a total of 3.6 liters of pleural fluid was removed. The patient died on the 6th postoperative day in a state of progressive shock, hypoxia, and anuria. Necropsy showed submucosal edema of the remaining large and small intestines, anasarca, and pulmonary atelectasis. Differential diagnoses of regional enteritis, acute nonspecific ileitis, infectious enterocolitis, iatrogenic accident, and allergic phenomena were considered. This case, however, was consistent with a diagnosis of capillary leak syndrome due to increased permeability of capillary membranes as manifested by hypovolemic shock, hemoconcentration, and anasarca in the absence of fluid overload, congestive failure, or blockage of lymphatic or venous channels. The cause of the capillary leakage producing massive edema of the bowel remains obscure. It is believed that this is an example of the rare, recently identified capillary leak syndrome which has so far not been reported as a postoperative complication of appendectomy.

5572 BOWEL TRANSIT-TIMES IN TWO POPULATIONS EXPERIENCING SIMILAR COLON-CANCER RISKS. *(E.)* Glober, G. A.; Klein, K. L.; Moore, J. O.; Abba, B. C. (Natl. Cancer Inst., Natl. Inst. Hlth., Bethesda, Md.). *Lancet* (7872):80-81, 1974.

To investigate the indirect relationship between dietary fiber intake and incidence of carcinoma of the colon suggested by the fact that as fiber is reduced, bowel transit time is lengthened and thus the risk for large intestine cancer would seem to increase, bowel transit time was measured in 86 men (50-75 yr old), 63 of whom were Japanese and 23 Caucasian, both groups living in Hawaii. Although the Japanese men shared the same risk for colonic cancer as did the Caucasians, the transit times were dissimilar: in the Japanese 32.3 hr with 1 stool/day as compared to 53.8 hr in Caucasians of the same age group. These differences could not be explained by body weight, surface area, number of bowel movements/day, occupation, or education. Results indicate, therefore, that bowel transit time is not related to the pathogenesis of colonic disease.

5573 ARE ELEMENTAL DIETS USEFUL IN BOWEL PREPARATION? *(E.)* Cooney, D. R.; Wassner, J. D.; Grosfeld, J. L.; Jesseph, J. E. (Indiana Univ. Sch. Med., Indianapolis). *Arch. Surg.* 109(2):206-210, 1974.

The efficacy of elemental diets and antibiotics in the preoperative preparation of the colon was evaluated in 90 Sprague-Dawley rats. Six groups of 15 animals each (8 males and 7 females) were used: the control group had no preparation and received standard rat chow, while the other 5 groups underwent a 4-day preoperative treatment with one of the special diets and with magnesium sulfate p.o. (200 mg/day) as a cathartic for the 1st 2 days. The diets consisted of (1) Vivonex; (2) Flexical (both elemental diets mixed with water to a final concentration of 1 calorie/ml); (3) clear liquids only; (4) clear liquids + i.m. kanamycin sulfate (15 mg/kg/day) and i.m. cephalothin sodium (50 mg/kg/day) 24 hr before operation and 72 hr after; and (5) clear liquids + antibiotics p.o. (10 mg neomycin sulfate and 50 mg lincomycin hydrochloride [Lincocin]). Partial colectomy and colon anastomosis were done on each animal. Observations on survival, weight changes preoperatively and 7 days postoperatively, mean tensile anastomatic strength, and the incidence of anastomotic leak and wound infection led to the following conclusions: (1) elemental diets or antibiotics were not superior to mechanical preparation alone; (2) elemental diets were as effective as orally administered antibiotics in decreasing the incidence of postoperative infection; (3) elemental diets did not prevent anastomotic leak or enhance anastomotic mean tensile strength; and (4) mechanical bowel emptying using clear liquids and cathartics remains the key to short-term preoperative colon preparation. In general, results here suggest that the added nutritional support of elemental diets may be of value, particularly in the chronic debilitated patient.

5574 CARCINOMA OF THE LARGE INTESTINE IN CHILDREN. *(E.)* Wolloch, Y.; Dintsman, M. (Tel Aviv Univ. Med. Sch., Israel) *Am. J. Surg.* 127(6):693-695, 1974.

Case reports are presented of cancer of the large bowel in 2 children, a 12-year-old boy and an 18-year-old girl. The boy experienced epigastric and periumbilical pain, anorexia, and loss of weight 3 weeks prior to hospitalization. Barium enema examination demonstrated an infiltrating lesion in the transverse colon, compatible with carcinoma, with prestenotic dilation of the bowel. At operation a tumor causing stenosis was found in the transverse colon with multiple metastases in the omentum, liver, peritoneum, and pelvis. On the 10th postoperative day, progressive jaundice occurred; he died 3 weeks later. The girl developed pain in the right iliac fossa and became constipated 1 year prior to admission. The pain subsided after treatment with laxatives and enemas, which she continued to use. One month before admission, she had a recurrence of lower abdominal pain, and fresh blood was observed intermittently in the stools. Rectosigmoidoscopic examination demonstrated a tumor 8 cm from the anal verge. At laparotomy, a mass the size of a fist was found at the rectosigmoid junction. Anterior resection of the rectosigmoid was performed along with transverse colostomy. After several months, intestinal function returned to normal. Sixteen years after operation, she had no symptoms referable to the gastrointestinal tract and no signs of recurrent disease. Cancer of the large bowel in children occurs very rarely (less than 1% occur in people under 30) and is characterized by a fulminating course and high mortality. In the majority of cases, cancer of the colon in children appears with no antecedent history of intestinal disease. The main reason for delay in establishing the diagnosis is the absence of a typical clinical picture in the majority of cases and the comparative rarity of the disease. The presenting symptoms can include: abdominal pain (90%), vomiting (40%), constipation (25%), rectal bleeding (18%), and weight loss (20%). The tumor may occur in any part of the colon, but the majority are found in the sigmoid colon. Barium enema and sigmoidoscopy represent the 2 most important tests for confirming the diagnosis. It is stressed that only an increased awareness of the possibility of carcinoma of the colon in children will lead to earlier detection of the disease and thereby to improvement in the generally poor prognosis in those cases.

5575 NONSPECIFIC ULCERS OF THE CECUM: REPORT OF TWO CASES. *(E.)* Lazarovitch, I.; Michowitz, M.; Lowenthal, M.; Solowiejczyk, M. (Tel Aviv Univ. Med. Sch., Israel) *Dis. Colon Rectum* 17(3):381-386, 1974.

Because of the rare occurrence of multiple ulcerations in the cecum, case reports of 2 such patients are presented to aid in accurate diagnosis. In a 32-yr-old woman who underwent surgery for the clinical diagnosis of acute appendicitis a large quantity of clear fluid was found in the peritoneal cavity. The cecal area was edematous, with an inflamed wall; palpation revealed a tumor 3 cm in diameter. Since malignancy could not be eliminated, right hemicolectomy was performed. The postoperative period was uneventful. The second patient, a 68-yr-old woman, showed melena and decrease in hemoglobin 1 week after treatment for femur injury due to a traffic accident. Two days later, at laparotomy, a large quantity of free air was found in the peritoneal cavity, with moderate inflammation of the peritoneum and some serous fluid and fibrin. The cecal wall was thickened. Because of suspicion of a malignant tumor, right hemicolectomy was performed. She died a week later of septic shock. No evidence of tuberculosis, amebiasis, or granuloma was found in these 2 cases. In general, since accurate diagnosis of this disease before operation is virtually impossible, treatment must be surgical. Colectomy should be performed in most cases because of the difficulty in excluding malignancy during an emergency operation and because suture of an inflamed and edematous wall may be hazardous. From the histopathologic point of view, the cases of nonspecific ulcer of the cecum do not resemble the more frequent cases of ulceration of the large intestine which are caused by ulcerative colitis, Crohn's disease, and other disorders.

5576 THE SPECTRUM OF LINCOMYCIN-CLINDAMYCIN COLITIS. *(E.)* Viteri, A. L.; Howard, P. Y.; Dyck, W. P. (Scott and White Clin., Temple, Tex.). *Gastroenterology* 66(6):1137-1144, 1974.

The clinical course, endoscopic findings, and roentgenographic features of seven cases of mild to severe colitis in previously healthy subjects after p.o. or parenteral adminstration of lincomycin or clindamycin were studied. The drugs used their routes and dosages were: i.m. lincomycin (600 mg/day) for 7 days; p.o. lincomycin (dosage unknown); and p.o. clindamycin (600 mg/day) for 9, 7, and 10 days. One subject presented a history of a similar but milder illness 2 yr earlier after an exposure to lincomycin. Mild reactions were characterized by bloodless, watery diarrhea without fever or leukocytosis, and minimal proctoscopic and radiological findings. Severe illness was associated with severe abdominal discomfort, fever, marked leukocytosis, and proctoscopic and roentgenographic evidence of severe mucosal ulceration, as well as pseudomembrane and pseudopolyp formation. The proctoscopic findings included edema, mucosal friability, pseudomembranes, superficial ulcerations, and pseudopolyps. The symptoms lasted from 4-8 weeks. After a clinical course of supportive management including Lomotil and i.v. fluid, all patients returned to normal health with reversal of the proctoscopic and roentgenographic abnormalities. No recurrence of symptoms has been noted during follow-up periods of several months to 3 yr.

5577 COLITIS CYSTICA PROFUNDA. *(E.)* Green, G. I.; Ramos, R.; Bannayan, G. A.; McFee, A. S. (Univ. Texas Med. Sch., San Antonio). *Am. J. Surg.* 127(6):749-752, 1974.

Features of a benign condition, colitis cystica profunda, which must be differentiated from colonic mucinous adenocarcinoma to avoid unnecessary radical operations are presented together with endoscopic views to aid in visual recognition. The 25 yr old female patient had passed excessive mucus and blood per rectum since age 8. She underwent hemorrhoidectomy without improvement in symptoms at age 16; 4 yr later, perianal condylomas were resected. Since then, the mucus discharge and rectal bleeding increased in frequency to several times per week. Proctoscopic examination revealed a 2 by 1 cm erythematous submucosal lesion extending 4 to 6 cm above the dentate line with several superficial ulcerations measuring 1 to 2 mm on the mucosal surface of the lesion. Under caudal anesthesia, local excision of the lesion was performed. The pathologist reported glandular mucus-filled cysts deep to the muscularis mucosae, some of which were lined with normal-appearing epithelium. Grossly the mucosa overlying the cysts in colitis cystica profunda, may show irregularly distributed areas of edema, hyperemia, hypertrophy, and atrophy with occasional superficial ulcteration or central umbilication. Microscopically, the cysts lie deep to the muscularis mucosae, and are lined with normal-appearing columnar epithelium or may merely be filled with mucus which stains faintly basophilic. Colitis cystica profunda could be of congenital origin, representing hamartoma formation; however, chronic inflammation has been accepted by most investigators as the primary etiologic factor. Physical findings in the 52 known cases of colitis cystica profunda were rectal mass or polyp, 40 cases; stenosis, 4; ulcerative colitis, 6; abnormal barium enema, 18; and rectal prolapse 5. Symptoms and signs of rectal bleeding occurred 33 times; diarrhea, 16; mucus stools, 17; pain, 9; tenesmus, 7; weight loss, 4; and previous rectal surgery, 12. Colitis cystica profunda should be included in the differential diagnosis of any rectal or colonic polypoid or intramural mass.

LARGE INTESTINE

Ulcerative Colitis

5608 THE IMMUNE COMPETENCE OF PATIENTS WITH INFLAMMATORY BOWEL DISEASE. *(E.)* Bolton, P. M.; James, S. L.; Newcombe, R. G.; Whitehead, R. H.; Hughes, L. E. (Welsh Natl. Sch. Med., Cardiff, Wales). *Gut* 15(3):213-219, 1974.

Immune competence was studied in 52 patients with Crohn's disease: 20 with ulcerative colitis, and 46 controls with benign gastrointestinal disease. According to clinical state of disease, the patient groups were further subdivided into asymptomatic and symptomatic groups. At time of testing 27 patients with Crohn's disease and 7 with ulcerative colitis were receiving steroid therapy. The 5 parameters of immune function tested were peripheral lymphocyte count, serum immunoglobulin levels (IgG, IgA, and IgM), lymphocyte response to phytohemagglutinin, Mantoux reaction, and dinitrochlorobenzene response. The peripheral blood lymphocyte count and lymphocyte response to phytohemagglutinin were similar in all patient groups. Serum IgA levels were elevated in Crohn's disease and were significantly higher in the symptomatic than in the asymptomatic subgroup. Mantoux and dinitrochlorobenzene responses were depressed only in symptomatic Crohn's disease patients on steroid therapy. Four patients with ulcerative colitis, 14 with Crohn's disease, and 33 controls subsequently underwent surgery. Serial immune testing during the 4th postoperative week showed that surgery had no effect on lymphocyte count, lymphocyte response to phytohemagglutinin, or serum IgG level in any group. Serum IgA values fell significantly in the Crohn's group after surgery and nonsignificantly in control patients. Serum IgM levels following surgery were increased in Crohn's disease patients and the symptomatic control subgroup. The results provide no evidence of impairment of immune competence in either Crohn's disease or ulcerative colitis.

5609 PROSPECTIVE STUDY OF OUTPATIENTS WITH EXTENSIVE COLITIS. *(E.)* Lennard-Jones, J. E.; Parrish, J. A.; Misiewicz, J. J.; Ritchie, J. K.; Swarbrick, E. T.; Williams, C. B. (St. Mark's Hosp., London, England). *Lancet* (7866): 1065-1067, 1974.

Extensive colitis in 171 patients was followed up on an outpatient basis for up to 7 yr. Death occurred in 7 patients. Carcinoma of the large bowel developed in 3, all of whom have remained well 7, 6, and 2 yr after operation. In these 3 patients dysplasia was observed on rectal mucosal biopsy, and no patient in this series developed carcinoma without this abnormality present. Epithelial dysplasia was noted on rectal biopsy in 11 other patients, 4 of whom underwent colectomy without evidence of carcinoma in the operative specimen. Colectomy was undertaken without mortality in 7 patients during a severe attack of colitis and in 22 electively. Surgical treatment is recommended for a patient with extensive colitis if a severe attack does not respond to medical treatment rapidly. Elective operation is advised for recurrent acute attacks or if the patient is persistently unwell. For a patient who is well, colectomy is advised if the cancer risk seems high; the factors to be considered are the length of history, the radiological appearances of the colon, and the presence of epithelial dysplasia observed in serial biopsies. Regular barium enema and colonoscopy should be included in the management, especially for patients with a history of more than 10 yr. Where circumstances prevent close follow-up, elective surgery for extensive colitis may be the safest course.

5610 ULCERATIVE COLITIS IN ELDERLY PATIENTS. *(E.)* Toghill, P. J.; Benton, P. (Gen. Hosp., Nottingham, England). *Gerontol. Clin.* 15(2): 65-73, 1973.

In a series of 303 patients with ulcerative colitis, 19 developed initial symptoms after the age of 65. Thirteen patients survived their initial attack of colitis. Most of these patients were treated medically with systemic and topical steroids together with salicylazosulfapyridine. Two patients achieved complete and lasting remission, 5 patients improved but subsequently developed relapses, and 3 remained unchanged. One patient underwent emergency proctocolectomy for perforation of the colon at the age of 67. Two deaths occurred after initial improvement of the colitis on medical treatment. Six patients died of acute toxic dilatation or perforation of the colon within 6 months of the onset of their colitis without experiencing any clinical improvement. None of the 19 patients developed colonic or rectal carcinomas. No examples of chronic liver disease, skin lesions, sacro-ileitis or ankylosing spondylitis were seen. Autopsy findings showed no specific features of ulcerative colitis in the elderly which would distinguish it from that seen in younger patients. One of the great difficulties in the diagnosis of ulcerative colitis in the elderly is its distinction from ischemic colitis. If the high mortality resulting from acute attacks of colitis in old age is to be improved upon, it seems likely that this will come from more accurate diagnosis and earlier resort to surgery.

5611 IMMUNOHISTOCHEMICAL CHARACTERIZATION OF LOCAL IMMUNOGLOBULIN FORMATION IN ULCERATIVE COLITIS.

(E.) Brandtzaeg, P.; Baklien, K.; Fausa, O.; Hoel, P. S. (Rikshosp., Oslo, Norway). *Gastroenterology* 66(6):1123-1136, 1974.

Immunohistochemical studies of the human intestinal immunocytes were performed in 8 patients with active ulcerative colitis and compared to 6 control patients without overt inflammation. The following characteristics existed in colon tissue specimens. (1) Persisting glands seemed to mediate a normal external transport of IgA and IgM via secretory component-producing columnar epithelial cells. (2) The average total numbers of mucosal IgA and IgM immunocytes in areas with persisting glands were raised 2.2 and 5.2 times, resp. (3) The average total number of mucosal IgG immunocytes in such areas was raised about 30 times, and the submucosa, in addition, contained a fairly dense immunocyte population with 84% IgG cells. In sections of directly fixed material, the connective tissue ground substance exhibited a diffuse, general fluorescence for IgG, which was especially intense in the basement membrane zones and vessel walls. This study suggests that a primary defect in the local secretory immunoglobulin system cannot explain the development of ulcerative colitis. A pronounced local IgG immunocyte response is associated with the pathogenesis of this disease, and regardless of the initiating etiological factor(s), these locally produced IgG antibodies may directly, or in cooperation with lymphocytes, be responsible for chronicity and recurrences.

5612 EVIDENCE OF CYTOTOXICITY IN ULCERATIVE COLITIS FROM IMMUNOFLUORESCENT STAINING OF THE RECTAL MUCOSA.

(E.) Ballard, J.; Shiner, M. (Central Middlesex Hosp., London, England). *Lancet* 1(7865):1014-1017, 1974.

Tissue immunofluorescent studies on mucosal complement in ulcerative colitis were made on 17 rectal mucosal biopsy samples from 11 patients with ulcerative colitis as well as biopsy specimens from 5 control subjects with diarrhea, constipation, or irritable bowel. In all colitis patients, the number of IgG-containing plasma cells was greatly increased, being highest in the most active disease cases. Increases in IgA plasma cells occurred in 10 of the 17 biopsy specimens, and IgM plasma cells were increased in 6. The increase in IgG plasma cells in the rectal mucosa suggests that the bacterial antigen stimulates local, not systemic, IgG production. There was also intense immunofluorescent staining of rectal mucosa connective tissue with IgG antisera, and a similar staining pattern was seen with the C3 component of complement in the colitis patients. This would indicate a reaction between these immunoglobulins and antigen resulting in a complement-binding complex. Such a complement deposit in the rectal mucosa suggests a cytotoxic reaction that may account for the pathological features of ulcerative colitis, such as ulceration.

5613 INTENSIVE INTRAVENOUS REGIMEN FOR SEVERE ATTACKS OF ULCERATIVE COLITIS.

(E.) Truelove, S. C.; Jewell, D. P. (Radcliffe Infirmary, Oxford, England). *Lancet* (7866):1067-1070, 1974.

Over a 5-yr period, a 5-day intensive intravenous regimen designed for treatment of severe ulcerative colitis attacks was used on 49 patients with this disease, some having their first attack, others being in relapse. The routine of this regimen was as follows: (1) Nothing except sips of water was allowed p.o. (2) At least 3 liters of fluid/day were given i.v., consisting of saline, glucose, blood, and sometimes parenteral feeding nutrients, with potassium supplementation as required. In addition, prednisolone-21-phosphate (60 mg/day), tetracycline (250 mg 4 times/day), and B vitamins as well as ascorbic acid were all i.v. administered. (3) A rectal drip supplied 100 mg hydrocortisone succinate sodium in approximately 120 ml saline twice daily. At the end of the course, 36 of the 49 patients were in complete remission. In a small proportion of patients who went into remission relapse soon after being switched to oral therapy after 5 days of the regimen, a second administration of the 5 day routine was attempted; but this procedure was almost universally unsuccessful. Such relapses are now regarded as a firm indication for urgent surgery. Four patients showed clinical improvement without remission, but they all required surgery within the next 6 weeks. The remaining 19 patients were unchanged, and the complete failure to improve was an absolute signal for emergency surgery. Likewise, any deterioration during the 5-day course was considered an indication for emergency operation without waiting to complete the course. This regimen gives a higher remission rate than has been recorded for other treatments; when used in treatment of first attacks of ulcerative colitis, a considerable chance of prolonged remission is seen. In this study, 2/3 of the first-attack patients who went into remission remained symptom-free during a follow-up period which averaged more than 3 yr.

5614 HISTOLOGICAL AND HISTOCHEMICAL CHANGES IN THE JEJUNAL MUCOSA IN ULCERATIVE COLITIS.

(E.) Binder, V.; Soltoft, J.; Gudmand-Hoyer, E. (Gentofte Hosp., Hellerup, Denmark). *Scand. J. Gastroenterol.* 9(3):293-297, 1974.

Jejunal biopsy specimens were obtained at the ligament of Treitz from 21 patients suffering from severe ulcerative colitis. Biopsy was repeated in 14 of the patients after remission of the colon disease. Eleven of the 21 patients with active colitis had minor changes in the villus patterns, while 10 showed a normal mucosal structure. The surface/volume ratio was found to be significantly lower in active than in inactive colitis even in the mucosal biopsy specimens without visible histological changes; and villus changes were not correlated to the degree of diarrhea nor to the degree of general disease (i.e. weight loss, anemia, fever). Judged by an estimation of the cell density in the lamina propria, there were no signs of inflammation in the mucosal stroma in active disease compared to inactive. Functionally, no consistent changes were found in the oxidative enzymes in the epithelial cells. Acid and alkaline phosphatases were inconsistently lowered in active as well as in inactive ulcerative colitis, and so were β-galactosidase and α-glucosidase. Possibly, the generally affected physical state is a cause of the changes in the small intestine in ulcerative colitis.

5615 COMPARISON OF CLINICAL AND MICROBIOLOGICAL PARALLELS IN PATIENTS WITH NONSPECIFIC ULCERATIVE COLITIS AND CHRONIC COLITIS. *(Rus.)* Smirnova, T. V.; Khodykin, A. V.; Ivanova, A. S.; Iartseva, I. 5622 UNUSUAL DIAGNOSTIC ASPECTS AND CURRENT MANAGEMENT OF PANCREATIC PSEUDOCYSTS. *(E.)* Gilman, P. K.; Gibbons, J. C.; Kaplan, M. S.; Juler, G. L. (Univ. California, Irvine, Sch. Med.). *Am. Surg.* 40(6):326-334, 1974.

Records of pancreatic pseudocyst patients (22-78 yr old) over a 9 yr period were reviewed to determine the frequency of correct diagnosis and best diagnostic methods as well as to clarify the best type of drainage to be used. In this study, 78 cases of pancreatic pseudocyst showed that 51 patients (65%) had surgical treatment and 27 patients (35%) were managed medically. Of the latter, 5 patients (18.5%) died and diagnosis was confirmed only at autopsy while the remaining 22 (81.5%) were discharged after 1-3 weeks of therapy. Postoperative problems appeared in 7 (20%) of the 37 patients treated by internal drainage, whereas 11 (78%) of the 14 with external drainage had significant complications; these 18 patients represented 36% of the 51 surgically treated cases. The overall rates of surgical morbidity (36%) and mortality (11.7%) were related to problems of sepsis, hemorrhage, fistula, and recurrence of the pseudocyst. However, when internal drainage was feasible, the morbidity and mortality rates were reduced to 20% and 5.5% resp. Methods used to confirm diagnoses were clinical findings and barium swallow 84%, and special roentgenographic studies for the remaining 16%. The latter were most useful, next to barium swallow used in 70% of the cases. Results here demonstrate that constant awareness, early diagnosis, and internal drainage of pancreatic pseudocyst are essential to reduce the complications and mortality rates of this disease.

5623 IMPORTANCE OF PATHOLOGIC STAGING IN THE SURGICAL MANAGEMENT OF ADENOCARCINOMA OF THE EXOCRINE PANCREAS. *(E.)* Hermreck, A. S.; Thomas, C. Y.; Friesen, S. R. (Univ. Kansas Med. Ctr., Kansas City). *Am. J. Surg.* 127(6):653-657, 1974.

A retrospective analysis of 348 patients with adenocarcinoma of the exocrine pancreas diagnosed at operation was performed to determine the effects of the stage of the disease on survival time with and without definitive surgical treatment. The extent of the disease as judged by operative and histologic findings at the time of operation was as follows: stage I, local disease only; stage II, invasion of surrounding tissues; stage III, regional node metastases; and stage IV, generalized carcinoma. The mean time of survival in 125 patients who underwent laparotomy and biopsy only for diagnosis was 0.15 year with no significant difference in survival time for the 4 different stages of diseases. The 172 patients who underwent palliative procedures had a mean survival time of 0.42 year. Survival time was significantly better for patients with stage I, stage II, and stage III diseases after palliative procedures, whereas with stage IV disease, survival was similar to that seen with laparotomy only. The 51 patients who underwent excisional procedures had a mean survival time of 0.95 year. Resections for stage I and stage II disease resulted in survival time of 1.4 and 1.2 years, respectively. However, for stage III and stage IV disease, the survival time after resection was almost identical to that observed with palliative procedures only. Resection procedures in patients with metastasis to lymph nodes have not resulted in any 5-year survivors, nor has the average survival been extended beyond that seen with palliatuve procedures. This study reveals that survival time for stage I and stage II disease is significantly longer after excision procedures, whereas for stage III disease palliative procedures yield survival expectations similar to those for resections.

5624 AN UNUSUAL CASE OF ADENOCARCINOMA OF THE PANCREAS.

(E.) Baer, J. W. (St. Luke's Hospital Center, Columbia College of Physicians and Surgeons, New York, N.Y.). *Am. J. Dig. Dis.* 19(7): 667-672, 1974.

Cystic calcified mucin-secreting adenocarcinoma of the pancreas, disclosed upon laparotomy of a 41 year old woman, is described to emphasize radiographic similarities and differences between two rare conditions: cystic adenocarcinoma and papillary cystadenocarcinoma of the pancreas. Laparotomy disclosed a large left upper quadrant cystic structure measuring 30 cm at its greatest diameter. A thick gelatinous material (2500 ml) was drained from the cyst. Due to attachment of the mass to the aorta, the lesion was not removed. Biopsy at surgery revealed pancreatic invasion by large signet-ring cells with clear cytoplasm and eccentric nuclei; these cells produced a large amount of mucin. Very dense hyalinized fibrous connective tissue containing lymphocytes and many calcium fragments composed the cyst wall. Death 10 months after surgery was due to extrahepatic biliary obstruction. The clinical presentation, the roentgenologic manifestation of a well circumscribed calcified mass, the lack of perineural invasion, and the paucity of distant metastasis suggested cystadenocarcinoma of the pancreas. Papillary fronds whose identification by angiographic and pathologic examination may lead to such a diagnosis are often destroyed by prolonged intracystic pressure. Calcium within the cyst wall did not help to differentiate between cystadenocarcinoma and mucinous adenocarcinoma of the pancreas. As in other areas of the gastrointestinal tract, the ability of a tumor to produce mucin appears to be the catalyst for calcium deposition. It may be that mucinous adenocarcinoma of the pancreas is a variant of cystadenocarcinoma of the pancreas.

5625 CYSTADENOMA OF THE PANCREAS. REPORT OF A CASE AND ITS ARTERIOGRAPHIC DIAGNOSIS.

(E.) Cheung, L.; Matolo, N.; Maxwell, J. G. (Univ. Utah Med. Ctr., Salt Lake City). *Gastroenterology* 67(1):155-158, 1974.

Cystadenoma of the pancreas in a 50 yr old white female is described in this report. The gross appearance of this neoplastic cyst at 1st laparotomy led to the diagnosis of pancreatic pseudocyst which was treated by internal drainage through a cystogastrostomy. Serum amylase was normal both before and after surgery. Postoperatively, the patient's condition deteriorated. At a 2nd hospital, the arteriographic appearance of the tumor's vascular pattern was helpful in differentiating cystadenoma from pseudocyst and carcinoma. Radical resection of this large cystic tumor was accomplished in a second operation by subtotal pancreatectomy, splenectomy, and wedge resection of the stomach. Cystadenoma and pseudocyst may be similar in gross appearance, but characteristic arteriographic features are exhibited by the cystadenoma which may be helpful in establishing a diagnosis. Total excision is the treatment of choice for this unusual condition.

5626 VAGOTOMY AND THE EXTERNAL FUNCTION OF THE PANCREAS.

(E.) Kramhoft, J.; Balslev, I.; Lindahl, F.; Backer, O. G. (Frederiksberg Hosp., Copenhagen, Denmark). *Scand. J. Gastroenterol.* 9(3):309-311, 1974.

In 18 patients operated on for duodenal ulcer with vagotomy (10 selective and 8 truncal) and with pyloroplasty, the exocrine function of the pancreas was evaluated using the amylase concentration, after administration of a test meal, in duodenal aspirate collected at 20 min intervals for 2 hr, before and from 3 to 18 months (average 6 months) after the operation. Since drainage procedure was identical in all patients and a preoperative examination of amylase secretion did not reveal any differences in the exocrine function of the pancreas, the vagotomy method used represented the only premeditated variable. No significant changes were found after selective vagotomy, but after truncal vagotomy there was a significant increase in the amylase concentration. Suggested causes for the intensified pancreatic function after truncal vagotomy include (1) hypersensitivity brought about by denervation; (2) changes in the release levels of cholecystokinin; (3) inhibitory fibers of the vagus being severed; and (4) changes in passage through the duodenum, due to the operation itself, thereby resulting in a change in enzyme concentration.

PANCREAS

Pancreatitis

5633 INFLAMMATORY MASSES FOLLOWING ACUTE PANCREATITIS: PHLEGMON, PSEUDOCYST, AND ABSCESS. *(E.)* Warshaw, A. L. (Massachusetts Gen. Hosp., Boston). *Surg. Clin. North Am.* 54(3):621-636, 1974.

Management of inflammatory masses which appear after acute pancreatitis depends on the specific nature of the lesion. Such masses fall into 3 categories: phlegmon, pseudocyst, and abscess, each of which is unique. Phlegmons are common, occur soon after onset of the attack, and usually resolve spontaneously over a few weeks during treatment for acute pancreatitis. Only in cases of long symptomatic persistence or development of secondary complications, such as abscesses, is surgical treatment necessary. Pseudocysts, apparently much less common, most often require drainage to abort symptoms or forestall complications. It is preferable to allow the pseudocyst to mature for 4 to 6 weeks to permit safe internal drainage by cystenterostomy. The incidence of abscesses after pancreatitis, 4% overall, increases with the severity of the attack and the degree of resulting tissue necrosis. It is felt that the abscess may result from secondary infection of a pseudocyst or phlegmon. Recognition or strong suspicion of pancreatic abscess requires immediate abdominal exploration and drainage.

5634 GALLSTONE PANCREATITIS. *(E.)* Kelly, T. R. (Akron City Hosp., Ohio). *Arch. Surg.* 109(2):294-297, 1974.

Over a 15 yr period, biliary tract surgery performed on 52 patients (average age 55 yr, 37 females and 12 males, 3 unidentified) with gallstone pancreatitis was marked by a minimum of complications and no mortality. In those patients operated on during the acute phase of the pancreatitis, the pancreas appeared to be either mildly or severely inflamed. In 35.7% of the patients with surgery after regression of symptoms, the pancreas appeared grossly normal. Cholelithiasis was present in all 52 patients, and the gallstones were located in the gallbladder in 49 (94.2%) patients, in the common bile duct in 11 (21.1%), and impacted in the ampullary area in 3 (5.7%). Operative procedures included cholecystectomy, operative cholangiography, and choledochostomy, as indicated. Of the 52 patients, 8 exhibited postoperative complications which included prolonged ileus, abdominal pain, persistently elevated serum amylase levels, wound infection, recurrent or mild pancreatitis, atelectasis, and delayed recovery. All of the patients were examined annually for the 1st 3 yr, and biannually thereafter. In the 1-15 yr postoperative follow-up, 8 of the patients died from causes unrelated to biliary-pancreatic disease. In 2 patients (4%), pancreatitis recurred: 1 related to choledocholithiasis 2 yrs after surgery, and 6 yr after operation with no apparent relation to biliary tract disease. Since the natural history of gallstone pancreatitis is one of frequent recurrence, the correction of the biliary tract disease should be performed on the initial hospital admission since deferring surgery puts the patient in jeopardy by allowing time for recurrent attacks of pancreatitis.

5635 PROGNOSTIC SIGNS AND THE ROLE OF OPERATIVE MANAGEMENT IN ACUTE PANCREATITIS. *(E.)* Ranson, J. H. C.; Rifkind, K. M.; Roses, D. F.; Fink, S. D.; Eng, K.; Spencer, F. C. (New York Univ. Med. Ctr., N.Y.). *Surg. Gynecol. Obstet.* 139(1):69-81, 1974.

To assess methods for the early identification of severe acute pancreatitis and evaluate the role early surgery, a 1 yr study was made of 100 atients with this condition. Pancreatitis was ssociated with alcoholism in 74, biliary tract isease in 14, and other causes in 12 patients. Fifeen patients died and 16 were seriously ill. Such eath or serious illness was correlated with 10 dmission findings pertaining to age; fluid retention; nd blood level changes in glucose, calcium urea itrogen, and the enzymes LDH and SGOT, as well as terial O_2 tension, hematocrit, and white blood ell count. Relation of these factors to morbidity nd mortality revealed that 2 deaths and 9 cases of erious illness occurred out of 79 patients with fewer han 3 of the 10 signs present, while there were 13 eaths and 7 serious illness cases out of 21 patients aving 3 or more of these 10 factors. These early bjective findings indicate clearly the gravity of volving acute pancreatitis and may permit the election of patients for the evaluation of new orms of therapy. To evaluate the role of early urgery, 10 seriously ill patients were randomly ssigned either to nonoperative management or to peration consisting of cholecystostomy, gastrostomy, ejunostomy, and wide pancreatic drainage. No deaths ccurred in either group; however, in the surgical roup, complications were more severe and the length f hospitalization was longer. Therefore, early perative management was not deemed to be of benefit n this small group.

536 ENDOSCOPIC PANCREATOGRAPHY IN MANAGEMENT OF RELAPSING ACUTE PANCREATITIS. *(E.)* Cotton, . B.; Beales, J. S. M. (Middlesex Hosp., London, ngland). *Br. Med. J.* 1(5908):607-611, 1974.

ndoscopic retrograde cholangiopancreatography (ERCP) as attempted in 31 patients suffering from repeated ttacks of acute pancreatitis. Pancreatograms were btained from 25 patients. Twelve showed definite surgical lesions" (obstructions, strictures, or seudocysts). In at least 3 patients, failure to obain a pancreatogram was due to obstruction of the ancreatic duct close to the papilla. Two patients ith pseudocysts developed a mild relapse of panreatitis after the pancreatographic procedure. Surical intervention based on the X-ray findings seemed eneficial in the short follow-up period. ERCP can be f value in deciding when surgery is advisable for atients with relapsing acute pancreatitis and in deermining the operative approach. This procedure eems to be the only way, short of surgery, to identiy a surgical lesion in the pancreatic duct. In some atients with parenchymal disease, ERCP may be the nly way of clearly showing the presence of gallstones. n cases of relapsing pancreatitis, particularly in hose with pseudocysts, no attempt should be made to utline the entire cyst, and the patient should be conidered for surgery within the next few days. ERCP hould always be an inpatient procedure.

637 THE EFFECT OF ISUPREL ON EXPERIMENTALLY-INDUCED PANCREATITIS IN THE DOG. *(E.)* avarro, L.; Wilk, P.; Rudick, J.; Drieling, D. A. Mt. Sinai Sch. of Med., City Univ. New York). *m. J. Gastroenterol.* 61(5):387-389, 1974.

The effect of Isuprel, a chronotropic drug, on survival time and on the extent of pancreatic lesions was studied in 23 mongrel dogs with experimentally produced pancreatitis. In 14 dogs, the Pfeffer method, i.e. a closed duodenal loop and gastroenterostomy, was used while in 7 animals, pancreatitis was produced by ligating the accessory pancreatic duct and injecting into the main duct a mixture of trypsin, blood, and bile. In both groups, approximately half the dogs were given i.v. Isuprel (1 μg/kg/min) via catheter in the vena cava. In the Pfeffer group, no significant differences were observed in either amylase level or pancreatic histology findings between the 6 dogs treated with Isuprel and the 8 controls; the survival time was 24 hours in all dogs. The gross anatomical findings consisted of a huge dilated, necrotic duodenal loop with a hemorrhagic pancreatitis involving the entire pancreas. In the second group, all 7 dogs were maintained under light anesthesia; 2 control and 2 Isuprel-treated dogs were sacrificed at 6 hours. The remaining animals were observed until they expired. These dogs died between 13 and 20 hours. A decrease in serum amylase levels were observed in both Isuprel-treated and control dogs over the course of the experiment. Portal pressures did not rise in the Ispurel-treated dogs, and they showed marked tachycardia. The decrease in serum amylase levels in the second group can be explained by the destruction of pancreatic tissue due to the sudden and acute hemorrhagic pancreatitis. It is concluded that the Isuprel did not reduce the volume and enzyme content of pancreatic secretion nor did it alter the pancreatic histology, mortality, or survival time. However, Isuprel did inhibit the increase in portal venous pressure following the injection of trypsin, blood and bile into the pancreas.

5638 FULMINATING PANCREATITIS IN PROLONGED PARENTERAL HYPERALIMENTATION: ONE CASE REPORT. *(Por.)* Faintuch, J.; Machado, M. C. C.; Birolini, D.; Lopes, L. H. C. (Fac. Med., Univ. Sao Paulo, Brazil). *Arq. Gastroenterol.* 11(2):91-94, 1974.

A severely malnourished 38-yr-old woman with dysphagia, frequent vomiting, heartburn, diarrhea, and radiological evidence of megaesophagus was fed totally i.v. after she had failed to respond to feeding through a gastrostomy tube and esophageal dilatation. Treatment was initiated by administering 1000 calories and 36 g amino acids daily, and plans were made to increase the total calories to 3000/day. However, after 4 days the patient developed mental confusion as a result of acidosis and hypovolemic shock; she displayed no concomitant abdominal symptoms. Despite efforts to treat circulatory disturbances and the use of artificial ventilation, her condition deteriorated and she died in less than 12 hr. Autopsy findings included acute necrotizing hemorrhagic pancreatitis, gallbladder dilation with no evidence of calculi, hydropic hepatocytic degeneration with remnants of *Schistosoma mansoni* ova, advanced megaesophagus, and severe hypertrophy of the tunica muscularis. Since there were no known factors which might have predisposed the patient to develop acute pancreatitis, it is suggested that an imbalance in amino acid metabolism might have been responsible for this complication, particularly since the patient was severely malnourished.

5639 FREE PROTEOLYTIC ENZYMES IN PANCREATIC JUICE OF PATIENTS WITH ACUTE PANCREATITIS. *(E.)* Geokas, M. C.; Rinderknecht, H. (VA Hosp., Sepulveda, Calif.). *Am. J. Dig. Dis.* 19(7):591-598, 1974.

To evaluate the postulation that inappropriate activation of zymogens in the pancreas plays an important role in the pathogenesis of acute pancreatitis, pancreatic juice from 4 patients with this disease was collected at 4 C from uncomplicated fistulae or by catheterization of the pancreatic duct and then was analyzed for concentrations of free trypsin, chymotrypsin, and elastase as well as the corresponding zymogens in the specimens. All samples contained free enzymes exclusively with the exception of the juice from 1 patient with a fistula who secreted zymogens and free chymotrypsin only during the first 2 postoperative days. The apparent lack of pancreatic trypsin inhibitor in the secretions of these patients, and earlier reports of low levels or absence of this inhibitor after abdominal operations, seems to point out a prerequisite in the development of acute pancreatitis. The trigger mechanism in the premature activation of pancreatic zymogens may be provided by autoactivation of trypsinogen or its activation by enzymes of the blood-clotting or fibrinolytic systems. Some evidence in support of such a hypothesis is presented.

5640 EXPERIMENTAL PANCREATITIS TREATED WITH GLUCAGON OR LACTATED RINGER SOLUTION. *(E.)* Condon, R. E.; Woods, J. H.; Poulin, T. L.; Wagner, W. G.; Pissiotis, C. A. (Med. Coll. Wisconsin, Milwaukee). *Arch. Surg.* 109(2):154-158, 1974.

One hundred twenty dogs were allocated randomly to five models of experimental pancreatitis and further assorted randomly within each model to four treatment groups. Pancreatitis models included the obstructed duodenal loop preparation and pancreatic duct injections of lactated Ringer solution or bile-trypsin solution at low or high pressures. Treatment groups were untreated controls; fluid-resuscitated animals; glucagon-treated animals; and animals that received both glucagon and fluids. Survival was recorded exactly up to 72 hours, at which time survivors were killed. Autopsy examinations recorded both gross and microscopic alterations in pancreatic structure. Glucagon treatment alone or in combination with volume resuscitation was not more efficacious than simple volume resuscitation in treatment of pancreatitis. In mild to moderate pancreatitis, glucagon therapy was associated with pancreatic hemorrhage not seen in either fluid-resuscitated or untreated control animals.

5641 BIOPSY OF THE PANCREAS. *(E.)* Isaacson, R. Weiland, L. H.; McIlrath, D. C. (Mayo Clin. Fdn., Rochester, Minn.). *Arch. Surg.* 109(2):227-230, 1974.

Biopsy of the pancreas for diagnosis of benign or malignant disease was performed in 527 patients during a ten-year period. The incidence of complication in patients who underwent laparotomy and biopsy of the pancreas was 6.2%. The incidence of complication presumed to be due to biopsy in patients who also underwent major pancreatic or biliary tract operations was 4.1%. Diagnosis made by microscopic examination of fresh-frozen sections correlated with subsequent review of permanent sections in all but one of the 527 cases. The results indicate that biopsy of the pancreas by wedge or needle technique and examination of fresh-frozen sections provide a reasonably safe and reliable way of establishing the diagnosis of pancreatic disease.

5648 LIVER DISEASE IN ASYMPTOMATIC CARRIERS OF HEPATITIS B ANTIGEN. *(E.)* Simon, J. B.; Patel, S. K. (Queen's Univ., Kingston, Ontario, Canada). *Gastroenterology* 66(5):1020-1028, 1974.

A 16 month prospective study of 6277 Red Cross blood donors in Canada was undertaken to determine the hepatic status of apparently healthy hepatitis B antigen (HB Ag) carriers. Out of 6277 donors, 12 (0.19%) HB Ag carriers were detected. Antigenemia was much more prevalent among prisoners (4 of 251, 1.6%) than among nonprisoners (8 of 6026, 0.13%). Of the 12 carriers, 2 who contracted acute viral hepatitis after blood donation recovered completely with resultant disappearance of antigenemia, and another carrier was lost to follow-up. In the remaining 9 chronic HB Ag carriers, neither symptoms nor signs of hepatic or other disease were evident. All were young adults who either abused drugs or had lived abroad where antigenemia is more prevalent than in North America. In 7 of the 9 carriers, liver function tests were moderately deranged. Liver biopsies from all 9 subjects were abnormal: 6 showed nonspecific focal or reactive hepatitis, one had lobular inflammation typical of acute viral hepatitis, and 2 revealed chronic aggressive hepatitis. Serial biopsies in a 10th asymptomatic HB Ag carrier who was not part of the above series showed transition from active lobular hepatitis to chronic persistent hepatitis during a 13 month period of study. Since this investigation showed that a wide spectrum of subclinical hepatic disease regularly accompanies the asymptomatic HB Ag carrier state in Canada, it is felt that further studies must be conducted to provide answers to clinically significant problems involving carrier blood donors.

5649 RAPID EVALUATION OF HEPATIC SIZE ON RADIOISOTOPE SCAN. *(E.)* Rosenfield, A. T.; Schneider, P. B. (Beth Israel Hosp., Boston, Mass.). *J. Nucl. Med.* 15(4):237-240, 1974.

Since hepatic enlargement is an index of liver disease, multiple single measurements of hepatic size were performed on 100 random liver scans from 67 patients (25-84 yr old, average 58) with abnormal livers studied over a period of 5 yr and from 33 normal liver control subjects (24-85 yr, average 69). Criteria used for normality (all had to be fulfilled) were normal SGOT, LAP and alkaline phosphatase levels; no tissue abnormality; and no focal abnormalities on scan. The best indicator of liver pathology was found to be a vertical measurement halfway between the xiphoid and right liver margin (i.e. between the right lateral liver edge and the midsternal line). An upper limit for normal can be chosen to provide an index of hepatic disease when exceeded. In this series, the upper limit was set at 15.5 cm, but this number may vary slightly with technique. Diagonal measurements, maximum vertical and horizontal measurements, and area calculations provided a less reliable upper limit in the series. The method outlined above provides a simple and accurate technique for radioisotope scan evaluations since it was proved empirically to be the most reliable index of liver pathology.

5650 HEPATIC DISORDERS ASSOCIATED WITH LIVER/KIDNEY MICROSOMAL ANTIBODIES. *(E.)* Smith, M. G. M.; Williams, R.; Walker, G.; Rizzetto, M.; Doniach, D. (King's Coll. Hosp. Med. Sch., London, England). *Br. Med. J.* 2(5910):80-84, 1974.

Recently a new autoantibody, liver/kidney microsomal antibody (LKM), has been recognized as a possibly useful marker in immunofluorescent tests for some liver diseases because LKM reacts mainly with hepatocytes and proximal renal tubules, with the antigen localized in microsomal membranes. LKM has been detected in 0.12% of all sera tested by the authors since December 1972. In this study, correlations were investigated between clinical conditions and the presence of LKM in the sera of 33 patients (16 male, 17 female). Although 7 of these patients had normal liver function tests, 26 of the 33 LKM-positive patients had clinical liver disease. These consisted of 15 with active chronic hepatitis, 7 with acute and 2 with subclinical hepatitis, and 2 with hepatocellular carcinoma. Most of the 33 patients had been retested for LKM periodically over 4 years, with persistently positive results. Sera were screened at 1:10 dilutions by indirect immunofluorescence with polyvalent anti-γ FITC conjugates. In view of the results here, LKM may make it possible to single out an active chronic hepatitis subgroup which differs from other groups. The most prominent features consist of a lower frequency of antinuclear antibody and smooth muscle antibody, a higher proportion of males, a relatively high incidence in children, and onset of the illness marked by jaundice.

5651 THE VARIABLE COURSE OF PRIMARY HEPATOCELLULAR CARCINOMA. *(E.)* Davidson, A. R.; Tomlinson, S.; Calne, R. Y.; Williams, R. (King's Coll. Hosp., London, England). *Br. J. Surg.* 61(5): 349-352, 1974.

A study was made of 85 patients (64 men and 21 women, aged 15-83 yr) with primary hepatocellular carcinoma. Abdominal pain, the commonest presenting symptom, had a mean duration of 18.2 months. Abdominal swelling due to hepatomegaly was another common presenting symptom present for several months and in one case 4 yr prior to diagnosis. Underlying liver diseases were present as follows: cryptogenic cirrhosis (21), alcoholic cirrhosis (14), hemochromatosis (12), active chronic hepatitis (2), primary biliary cirrhosis (1). In cirrhosis patients, the development of liver failure frequently led to the diagnosis of the complicating carcinoma. At diagnosis involvement of the lymph nodes in the porta hepatis or in the para-aortic regions was shown in 9 and metastases in more distant sites in 3 patients. In the 63 patients in whom the carcinoma was proven before autopsy, survival from time of diagnosis was 7.7 months. Of these 63, 26 received no specific therapy; their mean survival time was 3 months, with the exception of one 83-yr-old female with idiopathic hemochromatosis who survived 4 yr in good health. Of the remaining 37 patients, 14 underwent surgery; 13, cytotoxic therapy; and 10, radiotherapy with mean survival times of 14, 8.7, and 5.6 months, resp. Whether there was underlying cirrhosis made no significant difference to survival time as measured from time of diagnosis. Radioimmunoassay detected Australia antigen in the serum of 7 of 31 patients, only 1 of these not having underlying cirrhosis.

5652 IDENTIFICATION OF MONOHYDROXY BILE ACIDS IN INTRAHEPATIC CHOLESTASIS OF PREGNANCY.

(Ger.) Back, P.; Sjovall, K.; Sjovall, J. (Med. Clin., Univ. Freiburg, Germany). *Verh. Dtsch. Ges. Inn. Med.* 78:1626-1630, 1972.

Since i.v. administration of monohydroxy bile acids causes acute cholestasis in animals, determinations of these bile acids were made on plasma samples from patients with cholestatic jaundice of pregnancy and normal pregnant women. After preliminary purification, plasma bile acids were separated on a Sephadex LH 20 column into a conjugated fraction and a highly polar fraction containing sulfate esters of conjugated acids. Gas chromatography of these fractions showed that plasma from one patient contained conjugated 3β-hydroxy-5-cholenic acid instead of cholic, chenodeoxycholic, and deoxycholic acids found in the other plasma samples. Solvolysis of the sulfate ester fraction, followed by alkaline hydrolysis, revealed that lithocholic, 3β-hydroxy-5-cholenic, and ursodeoxycholic acids were present in patients' plasma and lithocholic acid was also present in normal controls. These results were confirmed by mass spectrometry of the methyl ester-trimethylsilyl ether derivatives. Cholic, chenodeoxycholic, and deoxycholic acids were identified in all plasma samples. Thus, monohydroxy bile acids and ursodeoxycholic acid are present in human plasma as sulfate esters of their conjugates. Further research is necessary to determine whether the presence of these acids is the cause or result of cholestatic jaundice of pregnancy.

5653 ANGIOSARCOMA OF THE LIVER IN A VINYL-CHLORIDE WORKER.

(E.) Lee, F. I.; Harry, D. S. (Victoria Hosp., Blackpool, England). *Lancet* 1(7870):1316-1318, 1974.

Massive edema, moderate ascites, and palpable liver, revealed upon examination of a 71 yr old man employed as a process worker for 20 yr in the manufacture of polyvinyl chloride from vinyl chloride monomer, suggested cirrhosis following further investigation. After his sudden death 2 weeks later, necropsy showed malignant hemangio-endothelioma (angiosarcoma) of the liver, an extremely rare tumor. In the 19 previously reported cases of this condition among workers in polyvinyl chloride plants, most had worked in that field for periods of 12-27 yr. Some of the reports stressed the concept of a multisystem involvement. The evidence appears strong that angiosarcoma of the liver is an occupational tumor and that vinyl chloride is the carcinogen. However, there is no evidence that the finished polymer, polyvinyl chloride, carries any risk. It may be that there is considerable individual variation in susceptibility to the hepatic effects of vinyl chloride; work in rats suggests that this sensitivity may be related to enhanced microsomal enzyme activity. Presently, many different avenues of research as well as investigation of records are being pursued to determine the scope of vinyl chloride effects.

5654 LIVER ULTRASTRUCTURAL FINDINGS IN PATIENTS INJECTED WITH THOROTRAST.

(E.) da Silva Horta, J.; Cristina, M. L.; Baptista, A. S. (Fac. Med., Lisbon, Portugal). *Proc. Int. Meeting Toxicity Thorotrast, 3rd, Copenhagen, Denmark, 1973* pp. 219-232.

Liver biopsies from 6 patients injected with Thorotrast (25-40 yr ago) were examined by electron microscopy. Alterations of the mitochondria (e.g. sizes up to 5 x 1.2 μ); smooth and rough endoplasmic reticulum; bile canaliculi (lumen distension); and hypertrophic Golgi complexes were found. Numerous multivesicular bodies were present. Thorotrast aggregates were found in the Kupffer and histiocytic cells, accompanied by needle like structures and surrounded by dense collagen, but Thorotrast was seldom seen in the hepatocyte. These findings were identical in all the cases and were more intense in patients injected the longest time ago. Although the lesions are not specific, it is suggested that they may represent an adaptive reaction to Thorotrast.

5655 CHARCOAL HAEMOPERFUSION IN THE TREATMENT OF FULMINANT HEPATIC FAILURE.

(E.) Gazzard, B. G.; Weston, M. J.; Murray-Lyon, I. M.; Flax, H.; Record, C. O.; Portman, B. N.; Langley, P. G.; Dunlop, E. H.; Mellon, P. J.; Ward, B.; Williams, R. (King's Coll, Hosp., London, England). *Lancet* 1(7870):1301-1307, 1974.

Twenty-two patients (aged 15-63 yr) with fulminant hepatic failure who deteriorated to grade-IV coma despite full supportive therapy were treated by repeated periods of hemoperfusion through columns containing activated charcoal. The procedure was well tolerated clinically. Eleven patients regained consciousness and 10 left the hospital. Follow-up liver biopsies in the first 3 patients at around 6 months after discharge showed restitution of the normal lobular architecture. Of the 11 treatment failures, hemorrhage was responsible for death in 3; and in 6, brain herniation secondary to cerebral edema was an important contributory factor. The column extracted most amino acids from the plasma; and during perfusion, arterial concentrations of phenylalanine, tyrosine, and methionine (amino acids known to be involved in the pathogenesis of the encephalopathy) fell significantly. The charcoal was coated with a biocompatible polymer, and there was no evidence of removal of coagulation factors. The extraction of platelets was below 30% in most instances, and in only 2 patients was there evidence that bleeding may have been precipitated by the hemoperfusion. These survival figures are in contrast to a previous survival rate of 10% in a series of 92 cases with fulminant hepatic failure and grade III or IV encephalopathy treated by full supportive meaures.

5656 PRIMARY LIVER TUMORS IN INFANCY AND CHILDHOOD: 41 CASES VARIOUSLY TREATED.

(E.)

Clatworthy, Jr., H. W.; Schiller, M.; Grosfeld, J. L. (Ohio State Univ. Coll. Med., Columbus). *Arch. Surg.* 109(2):143-147, 1974.

Forty-one infants and children (neonate to 17 yr, 20 girls and 21 boys) with primary tumors of the liver were evaluated as to cell type, age, sex, symptoms, diagnosis, therapy, and results. Malignant hepatomas were present in 26 (60%) of the patients, and there was one case of malignant teratoma and of mesenchymoma, while 13 lesions were histologically benign. Twenty-seven (66%) cases were diagnosed and treated under the age of 2 yr; 21 (51%) patients were in the 1st yr of life; and only 10 of the 41 patients were over 5 yr of age. No age difference was observed between those with benign and those with malignant lesions. Half of the patients were males, and most of the children were admitted with an asymptomatic abdominal mass. Tumor localization was accomplished by conventional roentgenographic and scanning techniques. Diagnosis was established at autopsy for 3 patients, and 38 underwent exploratory operation. Tumor resections were completed in 22 cases with 3 operative deaths. All patients with benign tumors and 3 of the 9 (33 1/3%) hepatoma patients have remained well five or more years. In the future, additional success may be foreseen by combining radiation, chemotherapy, and second-look resections.

Acute Viral Hepatitis

5672 AN OUTBREAK OF CHIMPANZEE ASSOCIATED HEPATITIS.

(E.) Hinthorn, D. R.; Foster, M. T.; Bruce, H. L.; Aach, R. D. (Univ. Kansas Med. Ctr., Kansas City). *J. Occup. Med.* 16(6):388-391, 1974.

The recently recognized association of primate-related hepatitis in humans led to investigation of an outbreak of acute hepatitis in 14 animal handlers at a municipal zoo. Two of the attendants acquiring hepatitis, however, had no contact with primates but were responsible for disposing of animal excreta from that area. Traced to 2 recently imported young chimpanzees, this epidemic was the first in which acute phase sera were screened for hepatitis B antigen (HB Ag) and its antibodies (anti-HB Ag) by using a radioimmunoassay technique. HB Ag was not demonstrated in the serum from the chimpanzees, the patients with hepatitis, or other attendants at risk. With serial serum testing, anti-HB Ag of low titer was found in the serum of only 1 of the 14 patients, an incidence similar to that in the community around the zoo. Epidemiologically, the outbreak had characteristics of short-incubation or type A viral hepatitis. Other examinations performed were SGOT, LDH, total bilirubin, and liver biopsies. At this stage, no distinction may be made between the spread of typical short-incubation hepatitis from chimp to man and the transmission to man of a different infectious agent primarily affecting subhuman primates. Findings here indicate that immunologically distinct infectious agents are capable of producing hepatitis in human and subhuman primates. The observation on the 2 hepatitis patients who handled only excreta argues strongly for fecal-oral transmission from chimpanzees to humans. Routine screening of newly-arrived primates for elevated SGOT might prove valuable in detecting animals capable of transmitting hepatitis to attendants.

5673 SUBSPECIFICITIES OF AUSTRALIA ANTIGEN.

(E.) Sama, S. K.; Krishnamurthy, L.; Gurdeep, S. (All-India Inst. Med. Sci., New Delhi). *Am. J. Dig. Dis.* 19(6):533-536, 1974.

The objective of this study was to determine the association, if any, between subtypes *ad* and *ay* of Australia antigen and the clinical outcome of infection (carrier state, acute hepatitis, or chronic hepatitis). Over a period of 2 yr, agar-gel diffusion and counterelectrophoresis techniques were used to identify subtypes *a*, *y* and *d* in 100 samples of HB Ag-positive serum from 76 cases of virus B hepatitis and 24 carriers. All sera were positive for the *a* determinant. Of the total, 67 samples were positive for the *y* determinant (and therefore for *ay*) and 33 for the *d* determinant (and thus for *ad*). Similar relative distribution of subtypes was found in cases of hepatitis and carriers. However, on evaluating the hepatitis group alone, a significant predominance of subtype *ay* was found in cases of acute hepatitis (41/48) and subtype *ad* (18/28) in cases of chronic hepatitis. This implies that infection with hepatitis B virus of subtype *ad* is more likely to lead to the sequelae of chronic hepatitis than infection with subtype *ay*.

5674 A PROSPECTIVE STUDY INDICATING THAT DOUBLE-ANTIBODY RADIOIMMUNOASSAY REDUCES THE INCIDENCE OF POST-TRANSFUSION HEPATITIS B.

(E.) Hollinger, F. B.; Werch, J.; Melnick, J. L. (Baylor Coll. Med., Houston, Tex.). *N. Engl. J. Med.* 290(20):1104-1109, 1974.

The efficacy of the double-antibody radioimmunoassay method (RIA-DA) in screening donor blood for the hepatitis B antigen (HB_s Ag, the antigen of the small 20-nm particle, which is also present on the surface of the large Dane particle) was compared with that of the Ausria solid-phase system using 227 recipients of blood transfusions. Of the 688 counterelectrophoresis-negative donor units tested, RIA-DA showed 2.6% to be positive for HB_s Ag, while the Ausria method showed only 1.5% to be positive. Approximately 70% of the 227 recipients were negative for HB_s Ag and antibody. Eight of these susceptible recipients received an RIA-DA positive unit of blood without receiving any anti-HB_s-positive donor units. In 7 of these patients, clinical hepatitis B subsequently developed or there was serologic evidence of exposure to hepatitis B virus. No anicteric or icteric cases of HB occurred among the 147 susceptible individuals who received RIA-DA negative blood. The Ausria method failed to implicate a positive donor in the cases of 3 susceptible patients who developed serologic evidence of exposure to hepatitis B virus or in the cases of two susceptible patients who developed clinical hepatitis B. The RIA-DA test is apparently the most reliable technique currently available for measuring HB_s Ag levels.

5675 ELECTRON MICROSCOPY AND IMMUNOELECTRON-MICROSCOPY OF CYTOPLASMIC HEPATITIS B ANTIGEN IN HEPATOCYTES.

(E.) Gerber, M. A.; Hadziyannis, S.; Vissoulis, C.; Schaffner, F.; Paronetto, F.; Popper, H. (VA Hosp., Bronx, N.Y.) *Am. J. Pathol.* 75(3):489-502, 1974.

Studies to determine hepatitis B antigen localization and the nature of the virus-like particles in hepatocytes of HB antigenemic patients were made by immunofluorescent and electron microscopic examinations of 29 liver biopsy and 4 autopsy specimens. Sources were 16 hepatitis B antigen carriers, 2 hepatitis B antigen seropositive patients with acute and 9 with chronic hepatitis, and 6 hepatitis B antigen seronegative persons. A varying number of hepatocytes showed numerous tublar and circular structures (20 to 30 nm diameter) in the cisternae of the excess smooth endoplasmic reticulum, and fluorescence which was cytoplasmic hepatitis B antigen-specific was seen. Such hepatocytes were found in 13 of 16 hepatitis B antigen carriers and in 4 of 9 patients with hepatitis B antigen-positive chronic hepatitis. Direct immunoelectronmicroscopy using peroxidase-labeled hepatitis B antigen antibody revealed that the intracisternal bodies and the surrounding membranes contained hepatitis B antigenic determinants. These bodies were an ultrastructural correlate of cytoplasmic hepatitis B antigen. It is suggested that they are virally coded coat material rather than the mature hepatitis B virus or its core. Immunoelectronmicroscopy using antibodies specific for the core and the coat of hepatitis B virus should demonstrate whether this suggestion is correct.

5676 HEPATOCELLULAR ULTRASTRUCTURE IN ASYMPTOMATIC HEPATITIS B ANTIGENEMIA. *(E.)* Sun, S. C.; Anderson, K. E.; Hsu, C. P.; Kau, S. L. (US Naval Med. Res. Unit No. 2, Taipei, Taiwan). *Arch. Pathol.* 97(6):373-379, 1974.

Liver biopsy samples from 21 Chinese military recruits from Taiwan (20-21 years old) with hepatitis B (HB) antigenemia were examined to determine histologic and cytologic abnormalities. The only common laboratory findings were mild elevation of SGOT and retention of BSP. Follow-up studies showed persistent HB antigenemia from 1.5 to 22 months. Light microscopic examination revealed 1 normal specimen, and changes associated with chronic persistent hepatitis in 3 cases, lobular hepatitis (9), and milder and less specific lobular abnormalities (8). In 9 cases, hepatocyte swelling was seen with ground-glass cytoplasm. There was no apparent correlation between the severity of the above histopathologic changes and the following changes observed by electron microscopy. Fine structural abnormalities were frequently present in the endoplasmic reticulum, mitochondria (swelling), and bile canaliculi (dilated with reduced or absent microvilli at the lumen surface). Nuclear changes were not prominent, and no intranuclear virus-like particles were found. Most striking was a pattern of proliferation of the endoplasmic reticulum associated with intracisternal filaments and particles which possibly represent an intracytoplasmic form of HB virus within the cisternae. The relation of this cytoplasmic alteration to HB virus replication deserves further study.

5677 VIRAL HEPATITIS, TYPE B. DNA POLYMERASE ACTIVITY AND ANTIBODY TO HEPATITIS B CORE ANTIGEN. *(E.)* Krugman, S.; Hoofnagle, J. H.; Gerety, R. J.; Kaplan, P. M.; Gerin, J. L. (New York Univ. Med. Ctr., N.Y.). *N. Engl. J. Med.* 290(24):1331-1335, 1974.

The results of studies of DNA polymerase activity and antibody to hepatitis B core antigen (HB$_c$ Ag) in serial serum specimens from immunized and unimmunized persons are presented here. These findings are correlated with the results of tests for SGOT activity, hepatitis B surface antigen (HB$_s$ Ag), formerly called Australia, and its antibody. The subjects were exposed to the MS-2 strain (or combined MS-1 and MS-2 strains) of hepatitis virus, parenterally, orally, and by contact exposure to hepatitis patients. Subsequent hepatitis B infection after parenteral exposure to MS-2 serum was detected by the appearance of hepatitis B surface antigen, which was identified as early as the 14th day by radioimmunoassay, on the 20th day by reversed passive hemagglutination, and on the 27th day by complement fixation. DNA polymerase activity was observed on the 41st day, and abnormal SGOT activity on the 59th day. The first antibody detectable was anti-hepatitis B core on day 59, followed by anti-hepatitis B surface, which was not detectable on day 146 but was present on day 203. DNA polymerase activity was detectable for at least 5 days but less than 2 weeks. In a patient who acquired hepatitis by contact, the hepatitis B surface antigen was first detected about 3 months after exposure, persisting for approximately 4 months. DNA polymerase activity, abnormal SGOT values and anti-hepatitis B core all became detectable 4.5 months after exposure. After oral exposure to combined MS-1 and MS-2 serum pool, there were abnormal SGOT levels from day 30 to 41, indicative of hepatitis A virus infection. Hepatitis B surface antigen was detected on day 75, 3 weeks before the SGOT levels again became abnormal on day 97. DNA polymerase activity was not detected. An oral exposure to the combined MS-1 and MS-2 serum pool, followed 6 months later by a parenteral exposure to the same serum pool, resulted in early evidence of hepatitis A infection. After parenteral exposure, there was detectable hepatitis B surface antigen 31 days later, detectable DNA polymerase activity on day 56, abnormal SGOT levels on day 70, and detectable anti-hepatitis B core on day 75. In a patient with hepatitis B virus infection and a subsequent chronic carrier state, hepatitis B surface antigen was detected on day 20 and persisted thereafter. DNA polymerase activity appeared transiently 1 to 2 months after exposure. Serial observations for 2 years after prevention of viral hepatitis, type B, with specific immune serum globulin revealed normal SGOT values, no detectable DNA polymerase activity, and no detectable hepatitis B small antigen. Three inoculations of heat-inactivated MS-2 serum at 2-month intervals were followed 4 months later by an inoculation of unheated MS-2 serum. During the 1.75-year follow-up period, SGOT values were normal, and DNA polymerase activity, hepatitis B surface antigen, and anti-hepatitis B core were not detectable. These findings indicate that DNA polymerase apparently can identify the period of peak hepatitis B virus replication.

5678 ANTIBODY TO HEPATITIS B CORE ANTIGEN. A SENSITIVE INDICATOR OF HEPATITIS B VIRUS REPLICATION. *(E.)* Hoofnagle, J. H.; Gerety, R. J.; Ni, L. Y.; Barker, L. F. (Bureau Biologics, Food Drug Admin., Bethesda, Md.). *N. Engl. J. Med.* 290(24):1336-1340, 1974.

Several populations were studied for the presence of hepatitis B surface antigen, its antibody, and the hepatitis B core antibody. Of 200 volunteer blood donors negative for hepatitis B surface antigen by either counterelectrophoresis or radioimmunoassay, 8 (4%) were positive for the surface antibody by passive hemagglutination and 2 (1%) were positive for hepatitis B core antibody. Of 363 hepatitis B surface antigen-positive samples obtained from apparently healthy persons, 307 were positive for the antigen by counterelectrophoresis and the remaining 56 were positive by radioimmunoassay. In the entire group, 355 (98%) were positive for hepatitis B core antibody. Among 100 chronic human carriers, 96 were positive for hepatitis B antigen by counterelectrophoresis and the remaining 4 were positive by radioimmunoassay. All 100 chronic carrier serum samples were positive for hepatitis B core antibody. Among 30 serum samples yielding false-positive reactions on radioimmunoassay, 1 was positive for both core antibody and surface antibody, and 1 was positive for surface antibody alone. A total of 10 of 16 blood donors implicated in post-transfusion hepatitis were positive for core antibody, including 4 who were positive for core antibody alone and negative for both surface antigen and surface antibody. The remaining 6 implicated donors were negative by all 3 tests. It is concluded that a test for antibody to hepatitis B core antigen may be a sensitive indicator of persistent viral replication even when subdetectable amounts of hepatitis B surface antigen are circulated.

5679 PARAPROTEINS WITH ANTIBODY ACTIVITY IN ACUTE VIRAL HEPATITIS AND CHRONIC AUTOIMMUNE LIVER DISEASES. *(E.)* Roux, M. E. B.; Florin-Christensen, A.; Arana, R. M.; Doniach, D. (Med. Educ. Ctr., Invest. Clin., Buenos Aires, Argentina). *Gut* 15(5): 396-400, 1974.

Of 27 patients with liver disease and cryoglobulinemia, 18 proved to have paraproteins. Six of these monoclonal immunoglobulins were shown to have antibody activity, directed to human gamma globulin, alpha$_1$-fetoprotein, smooth muscle, and mitochondria. Eight of the patients suffered from acute viral hepatitis, 5 of whom were HB Ag positive; in all these cases the monoclonal spikes were transient and their antibody activities were directed against IgG in 2 cases and alpha$_1$-fetoprotein in 1. Seven of the patients had active chronic hepatitis and in these the paraproteinemia persisted, though remaining quantitatively unchanged over several years. One of them had a cryoprecipitable monoclonal smooth muscle antibody. Three patients had primary biliary cirrhosis and in 2 of them monoclonal IgM mitochondrial antibodies were demonstrated. In three out of the 18 cases there was a double M-component. Since these monoclonal antibodies are directed to autoantigens not unlike the polyclonal ones usually seen in autoimmune hepatic diseases, it is suggested that the factor which triggers the uncontrolled plasma cell proliferation to produce paraproteins must contact cells from an already expanding clone.

5680 CELL-MEDIATED IMMUNE RESPONSE TO HEPATITIS B ANTIGEN IN PATIENTS WITH LIVER DISEASE. *(E.)* Gerber, M. J.; Phuangsab, A.; Vittal, S. B. V.; Dourdourekas, D.; Steigmann, F.; Clowdus, B. F. (Univ. Hlth. Sci./Chicago Med. Sch., Ill.). *Am. J. Dig. Dis.* 19(7):637-643, 1974.

Cell-mediated immune response to both serum and purified hepatitis B antigen (HB Ag) was measured in 151 subjects (including 14 controls) using the leukocyte migration inhibition test. Ninety-five percent of patients with HB Ag-positive acute viral hepatitis and 64% of patients with HB Ag-negative had positive leucocyte migration inhibition tests. Positive tests were rarely present in asymptomatic HB Ag carriers and were not found in patients with alcoholic liver disease or in normal controls. The data suggest that many patients with acute viral hepatitis in whom HB Ag is undetectable may have hepatitis B and that measurement of *in vitro* leucocyte migration inhibition to HB Ag is a sensitive index for establishing the etiological role of the antigen in the liver disease.

LIVER AND BILIARY TRACT

Chronic Hepatitis

5690 T AND B LYMPHOCYTES IN ACUTE AND CHRONIC HEPATITIS. *(E.)* DeHoratius, R. J.; Strickland, R. G.; Williams, Jr., R. C. (Univ. New Mexico, Sch. Med., Albuquerque). *Clin. Immunol. Immunopathol.* 2(3):353-360, 1974.

Peripheral blood thymus-dependent and bone marrow-dependent lymphocytes were measured in 50 healthy controls, in 40 hepatitis patients with or without hepatitis B antigen, and in 2 asymptomatic carriers of the antigen. A significant decrease in thymus-dependent lymphocytes occurred in patients with acute or chronic hepatitis but not in asymptomatic, hepatitis B antigen carriers. No significant difference was found between the proportion of liver thymus-dependent lymphocytes in antigen-positive patients and that in antigen-negative patients. The decrease occurred in all forms of acute hepatitis and was transient in patients who recovered. Thymus-dependent lymphocyte depression occurred in both chronic persistent and chronic aggressive hepatitis and did not correlate with disease activity or mode of treatment. In both acute and chronic hepatitis, decreases in thymus-dependent lymphocytes occurred independently of serum autoantibodies. The findings emphasize the potential importance of host responses in determining the outcome of viral hepatitis.

5691 ASSESSMENT OF ACTIVITY IN CHRONIC ACTIVE LIVER DISEASE: SERUM BILE ACIDS COMPARED WITH CONVENTIONAL TESTS AND HISTOLOGY. *(E.)* Korman, M. G.; Hofmann, A. F.; Summerskill, W. H. J. (Mayo Clin. Mayo Fdn., Rochester, Minn.). *N. Engl. J. Med.* 290(25):1399-1402, 1974.

Serum conjugates of cholic acid were determined by radioimmunoassay and compared with conventional tests in 38 patients (13-70 yr) during the course of chronic active liver disease that responded to treatment. There were 28 cases of chronic active hepatitis, 5 of subacute hepatitis with bridging, and 5 with multilobular necrosis. Therapy included placebo, prednisone, and prednisone and azathioprine. Sixteen patients subsequently relapsed when treatment was discontinued. At the time of diagnosis, values for these bile acids were always significantly elevated. With conventional liver tests, the values were still elevated in 33 of 38 patients, and this finding correlated with evidence of continuing histologic activity. At histologic remission of disease activity, these values were less than twice the upper limit of normal in all 22 patients who subsequently remained in remission without treatment, but were significantly higher in 9 of 16 who later relapsed. During relapse, serial determinations showed that elevation of serum conjugates of cholic acid preceded an increased SGOT. Findings indicate that serum concentrations of these bile acids in chronic active liver disease during and after therapy provide a more sensitive indication of active hepatitis than conventional liver tests.

5692 CHRONIC ACTIVE HEPATITIS WITHOUT HEPATITIS B ANTIGENEMIA IN RENAL TRANSPLANT RECIPIENTS. REPORT OF THREE CASES. *(E.)* Freiberger, Z.; Anuras, S.; Koff, R. S.; Bonney, W. W. (VA Hosp., Boston, Mass.). *Gastroenterology* 66(6):1187-1194, 1974.

Hepatic dysfunction is recognized as a complication in immunosuppressed patients after renal transplant, and progression of acute hepatitis B to hepatitis B antigen-positive chronic active hepatitis may occur. Over a 2 yr period, histologically confirmed chronic active hepatitis was observed in 3 patients 3 to 11 months after renal transplantation. None had circulating hepatitis B antigen in multiple serum samples tested by radioimmunoassay. Each patient had been treated with immunosuppressive therapy, consisting of prednisone and azathioprine, during the period in which liver disease became evident. Since a total of 32 patients underwent renal transplantation during the same period, this means approx. 10% developed clinically apparent chronic active hepatitis without hepatitis B antigenemia. Cyclophosphamide was substituted for azathioprine in all 3 patients, but no clear response to this alteration in therapy was observed, and in 1 patient, who developed hepatic failure, postnecrotic cirrhosis with esophagogastric varices was found on postmortem examination. The development of chronic active hepatitis without hepatitis B antigenemia after renal transplantation extends the spectrum of liver disease observed in immunosuppressed transplant recipients and raises new questions in the management of this hepatic disorder. The absence of antigenemia in the 3 patients reported here suggests that azathioprine, rather than hepatitis B infection, may possibly play a crucial role in the development of chronic active hepatitis.

5693 ACUTE SUBMASSIVE HEPATIC NECROSIS DUE TO METHYLDOPA: A CASE DEMONSTRATING POSSIBLE INITIATION OF CHRONIC LIVER DISEASE. *(E.)* Schweitzer, I. L.; Peters, R. L. (John Wesley County Hosp., Los Angeles, Calif.). *Gastroenterology* 66(6):1203-1211, 1974.

Acute submassive hepatic necrosis developed in a 49-yr-old woman with a 15 yr history of essential hypertension and a 4 yr history of diabetes mellitus.

Hypertension had first been treated with hydrochlorothiazide and then with reserpine, but 10 weeks before onset of symptoms, methyldopa (250 mg 3 times a day) had been substituted for reserpine. Other medications taken during the period immediately before onset of symptoms were diazepam (5 mg twice a day), indomethacin (25 mg as needed for back pain), and neutral protamine Hagedorn insulin injections for diabetes. The patient had received no blood transfusions in the past 2 yr. The reported adverse hepatic reactions to methyldopa administration include significant hepatic cell injury producing a syndrome with clinical, biochemical, and histopathological changes resembling acute viral hepatitis. The liver lesion was associated with a positive lupus erythematosus preparation, a positive direct Coombs test, and transient portal hypertension. Causal relation between methyldopa and the hepatic necrosis was established by an unequivocal response of transaminase activity to readministration of the drug. The most striking histological feature during the acute phase of the disease was extensive necrosis of liver cells in the periportal areas. The initial illness improved rapidly, and the patient has since remained asymptomatic. However, the following subsequent observations suggest that hepatic necrosis due to methyldopa may have initiated chronic liver disease: (1) the left lobe of the liver became persistently enlarged and firm after recovery from the acute liver injury; (2) liver scans 6 and 9 months after the acute episode revealed generalized mottling and a hypertrophied left lobe; (3) the liver tests did not return to normal for 9 months; and (4) follow-up liver biopsies revealed broadened periportal fibrosis at 6 months and collapsed stroma at 10 months after the acute submassive necrosis, although there was insignificant inflammatory activity at the time of the biopsy.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

5696 ALCOHOLIC STEATONECROSIS. II. PROSPECTIVE STUDY OF PREVALENCE OF MALLORY BODIES IN BIOPSY SPECIMENS AND COMPARISON OF SEVERITY OF HEPATIC DISEASE IN PATIENTS WITH AND WITHOUT THIS HISTOLOGICAL FEATURE. *(E.)* Birschbach, H. R.; Harinasuta, U.; Zimmerman, H. J. (VA Hosp., Washington, D. C.). *Gastroenterology* 66(6):1195-1202, 1974.

To evaluate the clinical significance of the presence of Mallory bodies in liver biopsy specimens, 100 alcoholic patients with clinical and biochemical evidence of hepatic disease were examined. Alcoholic hyaline was found in 32 patients. Other histological evidence of parenchymal injury as well as clinical and biochemical features indicated that the hepatic disease was somewhat more severe in patients with Mallory bodies than in those without. However, this study supports the conclusions of a previous one that the syndrome of alcoholic hepatitis can present without Mallory bodies in the liver; that the prognostic significance of the Mallory body *per se* is limited; and that correlation of clinical severity with histological abnormalities also requires consideration of other changes, especially necrosis. The term *alcoholic steatonecrosis, with or without Mallory bodies* is considered to be more acurately descriptive of the histological features of the syndrome than the commonly used term of *alcoholic hepatitis*.

5697 CLINICAL CORRELATIONS IN ALCOHOLIC PATIENTS WITH MANIFEST CIRRHOSIS. *(E.)* Bordalo, O.; Batista, A.; Geraldes, J.; Neto, F.; Mascarenhas, F.; Leitao, N.; Noronha, M.; Lamy, J.; Silva, P. E. (Inst. Path. Anat., Univ. Lisbon, Portugal). *Am. J. Gastroenterol.* 61(5):371-378, 1974.

To obtain data concerning the effect of duration and quantity of alcohol consumed on liver structure and function and to ascertain the most valuable clinical and laboratory parameters for the detection of active alcoholic liver disease, 213 male alcoholics (18-63 yr, average 40.1 yr) without complaints of liver disease and 50 patients with established alcoholic cirrhosis were studied. In the alcoholic group, 38.5% reported a normal dietary intake while the rest had anorexia and showed signs of malnutrition. On the basis of previous investigations, a daily intake of 160 g ethanol was established as the critical amount for hepatotoxicity. It was found that 1/2 of the alcoholic patients drank more than 160 g ethanol/day for over 10 yr. Biopsies on 103 patients revealed steatosis in 76%, inflammation in 73%, and fibrosis in 67%, while all three were present in 52%. In addition, signs of alcoholic hepatitis showed in 12 cases (11.6%), and cirrhosis in 2 patients. The liver function tests most frequently abnormal were BSP retention, prothrombin time, and the activities of the serum transaminases (SGOT and SGPT). Correlations established were: (1) no relation of morphological abnormalities to the amount of daily ethanol intake, but the frequency and severity of those abnormalities were related to the duration of alcoholism, as were also the amount and severity of fibrosis; and (2) severe fibrosis and cirrhosis were related to a daily intake of more than 160 g ethanol, but the establishment of cirrhosis was related both to a greater than 160 g daily intake and an alcoholism duration of more than 10 yr. In the study of 50 patients with alcoholic cirrhosis, similar relationships were observed between pathologic findings and the duration and quantity of alcoholic intake. This study indicates that liver biopsy might provide the necessary information as to active liver injury without clinical symptoms in alcoholics, but the inclusion of biopsy as part of a routine examination is not always possible. Comparison of functional data with morphological observations does not provide reliable parameters for the detection of liver involvement in the chronic alcoholic. The findings here show that the threshold of hepatic toxicity is lower than 160 g ethanol/day.

5698 LIPID DROPLETS IN FATTY LIVER. AN ELECTRON MICROSCOPIC STUDY ON ULTRASECTIONS OBTAINED BY A NEW CUTTING TECHNIQUE. *(E.)*

Petersen, P. (Rigshosp., Copenhagen, Denmark). *Acta Pathol. Microbiol. Scand.* [*A*] 82(2):255-263, 1974.

In this report, results are presented of a modified technique for cutting tissues rich in lipid, e.g. alcoholic fatty liver, without distortion or artefacts, for electron microscope examination. Liver biopsies were performed on 9 patients with suspected steatosis on the basis of clinical and biochemical findings; high alcohol consumption in 7 and maturity onset diabetes in 2 cases were the presumed causes. Diagnosis of steatosis was confirmed by light microscopy as 3 slightly and 6 moderately severe cases, with no signs of cirrhosis. In the survey sections, most of the lipid droplets were strongly osmiophilic and varied greatly in size, with diameters from 0.5 to 30 μ. In the non-osmiophilic vacuoles, fine networks stainable with toluidine blue were seen. Preparation for ultrasectioning consisted of cooling specimens and all cutting equipment to 8-10 C about 10 hours before sectioning. If the temperature rose to 14 C, cutting was not satisfactory. The thickness of the ultrasections was 3-600 A. After collection on grids and mounting with parlodion and carbon films, the sections were stained with zinc-uranyl-acetate and lead citrate. Advantages of this cold-cutting technique were: (1) flat, thin sections could be cut even when biopsies contained much fat; (2) larger areas could be cut, up to 0.5 mm for side lengths of squares, thus opening a possibility of evaluating larger areas in the electron microscope correlated to the survey sections; and (3) observation of many fat accumulations in one area was possible, thereby permitting the comparison of lipid droplets of a highly varied morphology. Ultrastructurally, the osmiophilic fat droplets often contained moderately electron-dense material of a homogenous nature. Just as often, the electron-dense material appeared in an irregular arrangement; and in such droplets, a concentrically arranged layer of this osmiophilic material was seen in the periphery with less electron-dense areas in between. In this capsule-like arrangement, a great deal of strongly electron-dense granules 100-1000 A were observed; they were also to a lesser degree found near the center of the droplet. In the non-osmiophilic vacuoles, a fine network was found which appeared very finely granular, not lamellar, and therefore did not seem to represent a remnant of the endoplasmic reticulum membrane. Near the periphery of the network, a capsule-like arrangement was present in which electron-dense granules similar to those in the osmiophilic droplets were observed. Many droplets showed transition stages, and many without osmiophilic material or structures were also seen. Histochemical staining showed lipid in the droplets, but the staining was heterogeneous in many of the droplets. Osmium tetroxide α-naphthyl showed the presence of triglyceride in many vacuoles; but in some, staining was lacking and in a few, a roughly meshed network was seen. Moreover, both Oil Red O and the osmium stain revealed fat and triglyceride between some hepatocytes. Since this was observed in the 10 μ sections, it is not possible to localize this fat in either the bile capillaries, the sinusoids, or perhaps both. Dilated intercellular spaces were seen with the electron microscope, but demonstrating fat in these spaces was not possible. The strongly electron-dense granules, identified by other workers as ferritin, do not appear to have the characteristics of ferritin granules in this study since they presented a varied morphology: round, oblong, rather pointed, and larger than those described. Further examination is necessary to elucidate the nature of these structures.

5699 VASCULAR COMPLICATIONS OF SUPERIOR MESENTERIC ARTERY INFUSION WITH PITRESSIN IN TREATMENT OF BLEEDING ESOPHAGEAL VARICES. *(E.)*

Berardi, R. S. (VA Hosp., Lexington, Ky.). *Am. J. Surg.* 127(6):757-761, 1974.

Two case histories are presented which demonstrate vascular complications occurring after selective catheterization of the superior mesenteric artery for vasopressin (Pitressin) infusion in the treatment of esophageal varices. The first case was a 50-yr-old chronic alcoholic man who was admitted with massive upper gastrointestinal bleeding. Emergency esophagogastroscopy revealed bleeding esophageal varices. Infusion via the superior mesenteric artery with vasopressin to control the bleeding was initiated at a rate of about 0.3 U/min. During 48 hours, he received a total of 60 units of vasopressin without adequate control of bleeding. A Sengstaken-Blakemore tube was inserted with temporary control of bleeding. After the arterial catheter was removed, his condition deteriorated and he died. Autopsy revealed gangrene of the entire small intestine with thrombosis of the superior mesenteric artery, and recent thrombosis of the portal vein. The second case was a 53-year-old chronic alcoholic man also admitted with massive upper gastrointestinal bleeding. Immediate control of bleeding was achieved with the Sengstaken-Blakemore tube. Eight days later, when the tube was removed, bleeding recurred, and superior mesenteric artery infusion with vasopressin was begun at a rate of about 0.3 U/min and continued intermittently over the next 4 days, the patient receiving a total of 70 units of vasopressin. Bleeding was not controlled, the arterial catheter was removed, the patient went into what appeared to be hepatic coma and approximately 24 hours later, he died. Thrombosis of both the superior mesenteric artery and the portal vein was revealed on autopsy, but no evidence of necrosis was seen in the small intestine. It is to be noted that vasopressin was started when both these patients were hyposensitive. It is concluded that utmost caution should be used with this modality of treatment in a patient who is in shock or who has hypotension secondary to hypovolemia, since the most frequent complication of arterial catheterization is thrombus formation.

5700 STUDIES CONCENING THE HYPERLIPIDEMIC ACTION OF ETHANOL. *(E.)* Schlamp, R.; Gartner, U.; Becker, K. (1st Med. Clin., Univ. Hamburg, Germany). *Acta Hepatogastroenterol.* 21(2):93-100, 1974.

5701 CIGARETTES, ALCOHOLISM AND CIRRHOSIS: AN EPIDEMIOLOGICIC STUDY. *(E.)* Resnick, R. H.; Khan, S. A.; Baum, R. A.; Sampliner, R. E. (Lemuel Shattuck Hosp., Boston, Mass.). *Gastroenterology* 66 (4):764, 1974.

LIVER AND BILIARY TRACT

Cirrhosis

5702 MEDIUM CHAIN TRIGLYCERIDES AND HEPATIC ENCEPHALOPATHY. *(E.)* Morgan, M. H.; Bolton, C. H.; Morris, J. S.; Read, A. E. (Dept. Med., Univ. Bristol, England). *Gut* 15(3):180-184, 1974.

The effect of oral administration of medium (C_{8-10}) and short chain (C_6) triglycerides to 21 cirrhotic patients was studied in relation to the transport of short and medium chain fatty acids through the blood-brain barrier with consequent possible neurotoxicity and resulting encephalopathy. In the first study, 11 cirrhotic patients and 11 volunteer controls fasted overnight and then received a single 60 ml p.o. dose of coconut oil in aqueous emulsion. A second study employed 12 cirrhotic patients and 3 controls given 30 ml coconut oil p.o. 3 times/day for 1 week. Although short chain fatty acid absorption was faster than medium, the overall absorption was rapid in all cases with maximum serum levels within 2 hr after administration followed by a fall in 7 hr. Significant medium chain fatty acid levels in the cerebrospinal fluid exhibited a like pattern. In general, cirrhotic patients showed serum medium chain fatty acid levels about 3 times higher than controls. Investigation as to arterial ammonia, chlorpromazine tolerance, and venous blood sugar levels revealed no significant changes. The electroencephalograph mean dominant frequency likewise showed no significant differences between cirrhotics and controls. Since the correlation of these findings do not demonstrate any deterioration in clinical or electroencephalograph status in cirrhotic patients following medium chain triglyceride administration (even in cases with previous tendencies to hepatic encephalopathy), this study offers no confirmation of suggestions that such administration may be contraindicated in patients with cirrhosis.

5703 BIOGENESIS AND PRODUCTION OF OESTROGENS IN MALES WITH CIRRHOSIS OF THE LIVER. *(E.)* Thijssen, J. H. H.; Lourens, J.; Donker, G. H. (Univ. Hosp., Utrecht, Netherlands). *Acta Endocrinol. (suppl.)* 184:31, 1974.

The frequent development of hyperestrogenism symptoms in male patients with cirrhosis of the liver instigated this study of the peripheral conversion of androstenedione to estrone and of testosterone to estradiol (along with estrone and estradiol production rates) in cirrhotic and normal males. Continuous double isotope infusion techniques and the urinary isotope dilution method were used. Cirrhotic patients showed a substantial increase in urinary production rates of estrone and estradiol. The peripheral conversion of androstenedione to estrone was also higher in cirrhotics than in normal controls, with a positive correlation between such conversion and the severity of the cirrhosis. The conversion of testosterone to estradiol was also greater in patients than in the controls. From preliminary *in vitro* studies and from the results of one experiment with catherterization of the hepatic vein during infusion, it seems highly unlikely that the cirrhotic liver itself is responsible for the increased aromatization of androgens to estrogens.

5704 PORTAL-SYSTEMIC ENCEPHALOPATHY AND PORTACAVAL ANASTOMOSIS: A PROSPECTIVE, CONTROLLED INVESTIGATION. *(E.)* Mutchnick, M. G.; Lerner, E.; Conn, H. O. (VA Hosp., West Haven, Conn.). *Gastroenterology* 66(5):1005-1019, 1974.

Over a 15 yr period, the frequency of portal-systemic encephalopathy was determined in 100 cirrhotic patients who were included in 2 prospective, randomly controlled investigations of prophylactic portacaval anastomosis: 40 patients with patent shunts, and 60 unoperated control patients. A second nonrandomized group of 118 patients, 39 with therapeutic portacaval anastomosis and 79 without, was also analyzed. Portal-systemic encephalopathy occurred in 20% of the patients before their inclusion in the study; after inclusion, during a mean period of follow-up of more than 4 years, 35% of the control patients and 53% of the shunted patients developed encephalopathy, an insignificant difference. Severe, chronic portal-systemic encephalopathy occurred in 20% of the shunted and in only 3% of the unshunted patients. Portal-systemic encephalopathy occurred during the first 6 months in patients with portacaval anastomosis, earlier than in unshunted patients, in whom it usually occurred during the first 18 months. The most common cause of portal-systemic encephalopathy after portacaval anastomosis was dietary protein, and encephalopathy attributed to this cause appeared in 30% of the shunted patients and in 11% of the unshunted patients. In the latter, the most common cause of portal-systemic encephalopathy was gastrointestinal hemorrhage (39% of the unshunted versus 13% of the shunted). The occurrence of portal-systemic encephalopathy before inclusion did not predict postshunt encephalopathy. Approximately 50% of those who had had portal-systemic encephalopathy before randomization developed it later, whether or not they had portacaval shunts.

5705 COMPARISON OF ASCITES ULTRAFILTRATE REINFUSION WITH PLASMA EXPANSION IN THE HEPATORENAL SYNDROME AND REFRACTORY ASCITES. *(E.)* Khan, S. A.; Baum, R. A.; Iber, F. L. (Tufts Univ. Sch. Med., Boston, Mass.). *Gastroenterology* 66(4):723, 1974.

5706 CHRONIC HEPATIC ENCEPHALOPATHY TREATED WITH ORAL LACTOSE IN A PATIENT WITH LACTOSE MALABSORPTION. *(E.)* Welsh, J. D.; Cassidy, D.; Prigatano, G.; Gunn, C. G. (Univ. Oklahoma Health Sci. Ctr., Oklahoma City). *Gastroenterology* 66(4):797, 1974.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

5707 TWELVE YEARS' EXPERIENCE WITH TRANSHEPATIC INTUBATION. *(E.)* Praderi, R. C. (Univ. Uruguay, Sch. of Med., Montevideo). *Ann. Surg.* 179(6):937-940, 1974.

In surgery of biliary stenosis, whether benign or malignant, the use of transhepatic drains constitutes an excellent safety procedure. The procedure described here is based on 12 years of experience with 60 patients. This technique involves (1) hepatic perforation so the major vessels are not injured, (2) fitting the tube to the lead, preferably by tying them together after perforation of the liver through the choledochostomy, and (3) making lateral perforations in the catheter. Postoperative management includes permanent clamping of the anastomosis only when no further leakage has been ascertained by cholangiogram, and removal of the tube 2-8 months postoperatively only if the course is uneventful. This technique has been employed for 42 patients with biliary cancers, 18 with postoperative strictures of the common bile duct, 1 with sclerosing cholangitis, and 1 with intrahepatic lithiasis. Of the 42 biliary cancers, only 12 were resected; 19 had supratumoral short-circuits and 11 were caliber-recorded. One death from hemorrhage occurred in a patient with a benign stenosis, and 3 patients developed right subdiaphragmatic abscesses which required drainage. Although leakage occurred frequently, none of the patients developed diffuse biliary peritonitis in the enterobiliary anastomoses.

5708 LIVER STRUCTURE AND FUNCTION IN CHOLELITHIASIS: EFFECT OF CHENODEOXYCHOLIC ACID. *(E.)* Bell, G. D.; Mok, H. Y. I.; Thwe, M.; Murphy, G. M.; Henry, K.; Dowling, R. H. (Hammersmith Hosp., London, England). *Gut* 15(3):165-172, 1974.

Hepatic function and histology were studied in 28 patients with cholelithiasis during treatment with chenodeoxycholic acid, as compared to 5 patients with gallstones given no medical therapy. Function was analyzed before and during treatment for periods from 6 weeks to 15 months in 25 patients receiving chenodeoxycholic acid (0.5 to 1.5 g/day) p.o. and in 3 patients given 0.25 g/day p.o. Serum bilirubin, albumin, and globulin levels were essentially normal during the treatment period, and there were no significant changes in the mean levels of 4 circulating liver enzymes studied: alkaline phosphatase, γ-glutamyl transpeptidase, SGOT, and isocitrate dehydrogenase. The clearance of a single bolus injection of BSP (5 mg/kg) showed no significant difference during the first 25 min, but during the following 35 min, clearance was more rapid in the treated patients than in the untreated. Mean fasting serum bile acid concentrations, both before and during treatment, were significantly greater than control values. Liver histology was interpreted as being not appreciably diferent in the 11 patients biopsied during treatment, 3 patients biopsied 3-4 months after completion of treatment and those patients not receiving chenodeoxycholic acid treatment. Of 2 patients on chenodeoxycholic acid however, 1 showed mild proliferation of bile ducts and 1 showed moderate to marked fatty change (in the absence of diabetes, obesity, or a history of alcohol intake). The results suggest no chenodeoxycholic acid hepatoxicity to man in doses of 0.5-1.5 g/day as used here, but more detailed long term-studies are required.

5709 SCLEROSIS OF THE EXTRAHEPATIC BILE DUCTS. *(E.)* Peck, J. J.; Kern, W. H.; Mikkelsen, W. P. (Hosp. Good Samaritan Med. Ctr., Los Angeles, Calif.). *Arch. Surg.* 108(6):798-800, 1974.

Evaluation of malignancy was made in this retrospective study of 13 patients (10 women and 3 men) with extrahepatic bile duct fibrosis or sclerosis seen over a period of 10 years. All were admitted with obstructive jaundice associated with elevated serum bilirubin and alkaline phosphatase levels; duration of symptoms ranged from 1 month to 6 yr. Hepatomegaly was present in all patients, but only 1 had fever, and none had eosinophilia. Operative reports described diffuse or beaded rope-like thickening of the common bile duct, either localized or extending the entire length. Histologic examination of the common bile duct in 8 patients definitely established a clear-cut diagnosis of sclerosing carcinoma. In the remaining 5 patients, although study was suggestive of malignancy, absolute diagnosis of carcinoma was not possible; however, autopsy examinations of 3 of these patients did establish carcinoma. The last 2 patients are still living but their diagnoses remain equivocal. This study demonstrates the difficulty of differentiating between benign disease and malignancy in the common bile duct. It is felt that the majority of diagnoses of primary sclerosing cholangitis may eventually be identified as carcinoma.

5710 EFFECTS OF CLOFIBRATE AND OF AN ESTROGEN-PROGESTIN COMBINATION ON FASTING BILIARY LIPIDS AND CHOLIC ACID KINETICS IN MAN. *(E.)*

Panveliwalla, D.; Ahrens Jr., E. H. (Mt. Sinai Sch. Med., City Univ., New York, N.Y.). *Gastroenerology* 66(4): 565-573, 1974.

The influence of clofibrate (2 g/day) and of estrogen plus progesterone (initial doses, 2.5 and 10 mg/day, resp.) on fasting biliary lipids and on cholic acid kinetics was studied in 10 recently cholecystectomized patients, 2 of whom had hyperlipidemia. Uninfected hepatic bile was collected periodically up to 4.5 months through a closed indwelling cystic duct catheter. Thus, the integrity of the enterohepatic circulation was preserved. Clofibrate (7 patients) and female sex hormones (3 patients) caused rises in the concentrations of biliary cholesterol and reductions in the bile acid levels, but no consistent changes in the phospholipid concentrations. Studies of cholic acid kinetics in 3 patients showed diminutions in the daily synthesis rates and pool sizes with both drugs. These changes in biliary lipids resulted in increased bile lithogenicity (bile supersaturated with cholesterol). Since an increased incidence of cholesterol gallstones would be predicted in patients habitually taking clofibrate and in women using oral contraceptives, cholecystography may be indicated prior to the institution of long term use of these drugs. Gastrointestinal symptoms in such patients should be evaluated in light of the increased risk of cholelithiasis.

5711 CHOLELITHIASIS IN CHILDHOOD. *(E.)*

MacMillan, R. W.; Schullinger, J. N.; Santulli, T. V. (Babies Hosp., Children's Med. Surg. Ctr. New York). *Am. J. Surg.* 127(6):689-692, 1974.

Surgical experience with cholelithiasis in 21 patients, 6-16 yr old, is presented. Vague distress or abdominal pain in the right upper quadrant was the most common complaint. Seven patients had jaundice. Roentgenologic examination was diagnostic of biliary tract disease in 19 of the patients. In 15 patients, calculi were demonstrated on oral cholecystogram or i.v. cholangio gram. Fifteen patients had hemolytic anemia. Congential hemolytic spherocytosis appeared in 5 cases. Five black children of the series either had sickle cell anemia or were heterozygous for hemoglobin S and C. Thalassemia major was an associated condition in 2 patients; thalassemia minor in 1; pyruvate-kinase deficiency in 1; and glucose-6-phosphate dehydrogenase deficiency in 1. Pathologic diagnosis was based on histologic examination: the majority of patients (52%) had evidence of mucosal destruction of the gallbladder with round cell infiltration and fibrosis indicative of chronic inflammation. Seven patients had a normal gallbladder, despite the presence of stones. Three patients had subacute cholecystitis. Of the patients with chronic cholecystitis, 73% were symptomatic; of the patients with a normal gallbladder, 71%. Cholelithiasis in every patient was treated by cholecystectomy. There were 5 choledochotomies, 2 of which revealed stones. Postopertive complications occurred in 4 patients: pneumonia in 2; thalassemia major in 1 with a decrease in hematocrit level; transient hematobilia in 1 with spherocytosis after choledochotomy, which subsided spontaneously. The peak incidence of gallstones occurred in patients between 10 and 13 years of age. Oral cholecystography was the diagnostic method of choice. These data indicate once the diagnosis of cholelithiasis is established, the treatment of choice is cholecystectomy. If indicated for hematologic reasons, splenectomy may be performed at the same operation with little increased risk to the patient.

5712 THE EFFECT OF CHOLECYSTECTOMY ON OESOPHAGEAL SYMPTOMS. *(E.)*

Barker, J. R.; Alexander-Williams, J. (North Devon Infirm., Barnstaple, England). *Br. J. Surg.* 61(5):346-348, 1974.

A prospective study was made of 225 patients with gallbladder disease treated by cholecystectomy. Of these, 77 (34%) complained of esophageal symptoms; after cholecystectomy 44 (20%) continued to have these symptoms. Before cholecystectomy, 64 complained of heartburn; 47 of reflux; and 10 of dysphagia. After cholecystectomy, 36 complained of heartburn; 29 of reflux; and 9 of dysphagia. Patients in the 50 to 59 yr age group had the highest incidence of esophageal symptoms before cholecystectomy and lowest rate of cure of symptoms after cholecystectomy. In patients with reflux on barium studies and/or an enlarged hiatus at operation, the incidence of esophageal symptoms was 60%; less than 20% of these were improved by cholecystectomy. Esophageal systoms were less common in men (27%) than in women (37%), but only 29% of the men were cured by cholecystectomy, as compared with a 45% cure rate in women. The findings support the hypothesis that there is an association between esophageal symptoms and gallbladder disease and that in some cases cholecystectomy may improve these symptoms.

5713 BILIARY LIPID SECRETION BEFORE AND AFTER CHOLECYSTECTOMY IN AMERICAN INDIANS WITH CHOLESTEROL GALLSTONES. *(E.)*

Alder, R. D., Metzger, A. L.; Grundy, S. M. (Natl. Inst.

Arthritis, Metabolism, Digestive Dis., Phoenix Indian Med. Ctr., Ariz.). *Gastroenterology* 66(6):1212-1217, 1974.

The effects of cholecystectomy on the hepatic secretion rates of biliary lipids and the relative lipid composition of hepatic bile were examined in 8 American Indian patients (7 female, 1 male) with cholesterol gallstones. Using a marker dilution technique, the hepatic secretion rates of cholesterol, bile acids, and phospholipids were measured during continous duodenal infusion of a liquid formula containing fat, carbohydrate, and protein before and several months after cholecystectomy. The infusion procedure was used to stimulate enterohepatic circulation of bile acids, during which the gallbladder does not contribute significantly to bile flow. Under these conditions, both pre- and postoperative results may be expected to reflect steady state hepatic bile secretion. Before surgery, the patients secreted hepatic bile that was more lithogenic than that in a group of white women without stones. When bile was sampled under identical conditions after cholecystectomy, there was no change in biliary lipid composition or in hepatic secretion rates. Thus contrary to previous reports, cholecystectomy apparently does not correct the defect leading to lithogenic bile in these patients.

5714 SUBDIAPHRAGMATIC ABSCESSES AFTER HEPATIC SURGERY. *(Rus.)* Shapkin, V. S. (Vladivostok Med. Inst., USSR). *Klin. Khir.* (7):6-9, 1973.

5715 NONOPERATIVE EXTRACTION OF RETAINED BILIARY TRACT STONES REQUIRING MULTIPLE SESSIONS. *(E.)* Burhenne, H. J.; Richards, V.; Mathewson, Jr., C.; Westdahl, P. R. (Children's Hosp., San Francisco, Calif.). *Am. J. Surg.* 128 (2):288-292, 1974.

5716 CHRONIC ACALCULOUS CHOLECYSTITIS. *(Rus.)* Milonov, O. B.; Smirnov, V. A.; Kurganov, A. S. (All-Union Sci. Res. Inst. Clin. Exp. Surg., Moscow, USSR). *Khirurgiia (Mosk.)* (10):94-99, 1973.

5717 TWO CASES OF ASEPTIC NECROSIS OF THE EXTRAHEPATIC BILIARY TRACT FOLLOWING CHOLANGIOGRAPHY DURING SURGERY. *(Fr.)* Popovivi, G. I.; Andreoiu, C.; Mocanu, A.; Onofrei, T.; Potirniche, A. (Dept. Surg., Becau, Rumania). *Lyon Chir.* 70(3):199-201. 1974.

5727 THE ORIGIN OF HUMAN FECAL ALKALINE PHOSPHATASE. *(E.)*

Horrigan, F. D.; Danovitch, S. H. (Washington Hosp. Ctr., D.C.). *Am. J. Dig. Dis.* 19(7):603-608, 1974.

Fecal alkaline phosphatase activity may derive from biliary secretions, desquamated intestinal epithelial cells, and/or colonic flora. To determine bacterial and biliary contributions, alkaline phosphatase activity in stool specimens from 6 adult patients was compared with the activity in human bile (2 subjects) and in small intestinal mucosal homogenates (12 subjects). Fecal activity was similar to that of jejunal mucosa in respect to specific activity, Michaelis-Menten constants, L-phenylalanine inhibition, and electrophoretic mobility on polyacrylanide gel. It is concluded therefore that fecal alkaline phosphatase activity is predominantly derived from the small intestine, which means that stool specimens may provide a potential source of the intestinal isoenzyme for study and also may have some diagnostic significance.

5728 ROENTGENOLOGIC MANIFESTATIONS OF GASTROINTESTINAL SCLERODERMA. *(E.)*

Kolar, J.; Drugova, B.; Stava, Z. (Charles Univ. Med. Fac., Prague, Czechoslovakia). *Acta Univ. Carol.* [*Med.*], *(Praha)* 17(7/8):595-616, 1973.

Repeated x-ray examinations were made over a 15 yr period in a group of 122 patients (109 females and 13 males, aged 11-71 yr) suffering from confirmed scleroderma. A general incidence of 94.2 % of positive radiographic findings using liquid barium was found after repeated investigations on the patients and comparisons of their events. Eighty patients were classified as having scleroderma, mostly generalized or polytopic except in 4 circumscribed cases; 1 patient had a rapidly progressive malignant scleroderma; 42 had acrosclerosis with Raynaud's phenomenon. Esophaegeal changes are the most common and radiologic findings include prolonged transit time through the esophagus, tendency for the esophagus to stay open after the bolus of barium has passed, formation of an air-fluid column, disappearance of the mucosal folds as the severity of the esophageal involvement increases, retention of barium with dilatation of the lumen, peptic esophagitis of the lower third, sliding hiatal hernia, and esophageal cancer. Involvement in the stomach may be indicated by dilation and delayed emptying, occasionally by a narrowing or spasm in the antrum of the stomach, and by marked aerogastria. However, no specific changes in the stomach were noted which would allow diagnosis to be made without additional proof obtained by endoscopy or microscopic examination. The small bowel was the second most commonly involved section of the gastrointestinal tract in scleroderma. Roentgenologic examinations showed dilatation of the small bowel with abnormal air filling and narrowing in the distal portion of the duodenum. The sclerodermic involvement of the colon remains uncertain regarding incidence and diagnostic criteria. The colon may appear atonic or dilated or there may be alternating areas of sacculation and rigid narrowings with thickened longitudinal folds in the narrowed segments. No immediate correlation between the extent of gastrointestinal and dermal involvement and positive gastrointestinal symptoms could be made. Follow-up radiological studies aid in assessing the general prognosis of the disease.

5729 ESSENTIAL FATTY ACID DEFICIENCY IN PATIENTS WITH LESIONS OF THE GASTROINTESTINAL TRACT.

(E.) Wapnick, S.; Norden, D. A.; Venturas, D. J. (Dept. Surg., Univ. Rhodesia, Salisbury). *Gut* 15(5): 367-370, 1974.

To analyze previous reports of deranged ratios of some unsaturated fatty acids in serum phospholipid after extensive bowel resection and of changes in the ratios of trienoic to tetraenoic acids as indicative of essential fatty acid deficiency in rats, this study was undertaken on 14 patients with small intestine resection, 10 patients with carcinoma of the esophagus, and 28 normal controls, all Rhodesian Africans on the traditional local maize diet. Tests for total serum lipid and for the relative amounts of unsaturated fatty acids (oleic, linoleic, linolenic, arachidonic, and eicosatrienoic) in serum lipids showed that both groups of patients had patterns of unsaturated fatty acid ratios suggesting essential fatty acid deficiency. Although some indications of such fatty acid deficiency appeared in the controls, the difference between patients and controls was significant. However, in the resection patients, there was no correlation between the extent of intestinal removal and the extent of change in the unsaturated fatty acid pattern. It is not known what damage (if any) such an essential fatty acid deficiency can do to the human, but these compounds have been shown to play a role in the maintenance of the cell membrane integrity which may affect both erythrocytes and mitochondria. Therefore, results seen here may indicate a case for supplementation of the low fat diet normally recommended with small amounts of unsaturated fat.

5730 AN UNUSUAL FORM OF MACROAMYLASEMIA. *(E.)*

Berggren, T.; Levitt, M. D. (Univ. Minnesota Hosp., Minneapolis). *Gastroenterology* 67(1):149-154, 1974.

In previously studied macroamylases, the molecular weight was considerably larger than normal serum amylase and was therefore easily documented by crude gel filtration techniques. This report describes a persistently elevated serum amylase level resulting from an unusual macroamylase which was only marginally larger than normal, found in a 69-yr-old housewife. However, the slightly increased size of this enzyme markedly influenced its renal clearance; and the existence of this macroamylase was first suspected because of the patient's consistently low urinary amylase to creatinine ratio. Although normally macroamylasemia is characterized by a normal or low urinary amylase in contrast to elevated serum amylase, the mildly elevated rates of urinary excretion seen here probably reflect the slow but appreciable rate of glomerular filtration of the relatively small-sized macroamylase when ordinarily the glomerulus is totally impermeable to larger forms of macroamylase. Careful gel filtration study was required to document the small increase in size of this enzyme. Isoelectric focusing showed the macroamylase to have a lower isoelectric point than did the 2 major components of normal serum amylase. Since previous studies have suggested that salivary amylase was cleared more slowly by the kidney than pancreatic amylase, the patient's saliva was diluted 1:50 and chromatographed to determine whether the serum amylase might represent her salivary amylase. This possibility was excluded by results which showed that her serum amylase eluted more rapidly than did the salivary amylase. Finally, if as is presumed the serum amylase levels in macroamylasemia are largely determined by the amount of binding substance in the serum, the wide swings of serum amylase levels observed in this patient over a period of several days suggest that there were rapid fluctuations in the serum concentration of this amylase-binding substance.

5731 RADIOIMMUNOLOGICAL MEASUREMENTS OF BACTERIAL ANTIBODIES. II. HUMAN SERUM ANTIBODIES REACTIVE WITH Bacteroides fragilis AND Enterococcus IN GASTROINTESTINAL AND IMMUNOLOGICAL DISORDERS.

(E.) Brown, W. R.; Lee, E. (Veterans Administration Hosp., Denver, Colo.). *Gastroenterology* 66(6):1145-1153, 1974.

In this study the normal concentrations of antibodies of 3 Ig classes to members of 3 genera of intestinal bacteria and the levels of these antibodies in some diseases were determined. Serum antibodies to *Bacteroides fragilis* and an *Enterococcus* species were measured by a radioimmunological technique similar to that used for measurement of antibodies to *Escherichia coli*. Concentrations of IgG, IgA, and IgM antibodies were determined in healthy subjects and in several groups of patients with gastrointestinal disorders. In healthy subjects, the concentrations of antibodies within each immunoglobulin class to *B. fragilis*, *Enterococcus*, and *E. coli* were of the same order of magnitude, despite marked differences in total, numbers of these organisms in contents. IgG and IgM antibodies quantitatively predominated over IgA antibodies. In gastrointestinal disorders, concentrations of antibodies to *Enterococcus* were normal or only moderately elevated. Concentrations of antibodies to *B. fragilis* often were elevated particularly in regional enteritis and chronic ulcerative colitis where increases in all 3 classes of antibodies of as much as 14 times were observed; antibody levels were roughly correlated with severity and pyogenic complications of these diseases. More moderate antibody elevations were found in patients with nontropical sprue, small bowel bacterial overgrowth, and chronic liver diseases. IgG antibodies to *B. fragilis*, as to *E. coli*, were elevated in patients with selective deficiency of serum and secretory IgA. Results of these studies provide evidence that: (1) concentrations of serum antibodies to intestinal bacteria are not influenced by the relative numbers of various bacteria inhabiting the intestine; (2) serum IgG and IgM antibodies to the bacteria studied are quantitatively greater than IgA antibodies; (3) increased concentrations of antibodies to *B. fragilis* in the chronic inflammatory bowel diseases most likely are consequences of the diseases, but a pathogenetic role of *Bacteroides* is a possibility; and (4) absence of IgA from intestinal fluids might result in increased synthesis of serum IgG antibacterial antibodies.

5732 THE BACTERIAL ETIOLOGY OF PNEUMATOSIS CYSTOIDES INTESTINALIS.

(E.) Yale, C. E.; Balish, E.; Wu, J. P. (Univ. Wisconsin Med. Sch., Madison). *Arch. Surg.* 109(1):89-94, 1974.

The natural course of pneumatosis cystoides intestinalis was studied in 73 germ-free Sprague-Dawley rats of both sexes, monocontaminated by either an i.p. (7.9 x 10^8 viable cells/ml) or submucosal (7.9 x 10^4 viable cells/ml) injection of a pure culture of *Clostridium perfringens*. Unsuccessful efforts were made to produce the disease in 10 germfree rats by similar monocontaminations with each of nine other species of bacteria, including *Escherichia coli* and *Enterobacter aerogenes*. The results showed that at least one species of bacteria, *C. perfringens*, could consistently produce the disease in germfree rats, with lesions similar in all respects to those found in humans. The disease was of limited duration: it took several days for the pneumatosis cystoides intestinalis to develop, and the intensity of the reaction appeared to be decreasing by 43 days. The disease did not occur in any of the controls that were unoperated but were monocontaminated with *C. perfringens*. Thus, it is believed that bacteria must come into contact with some traumatized tissue for the condition to occur. Appearance of gas cysts in the wounds after i.p. but not after i.m. injection suggests that the appearance of the lesions is related to the concentration of the organisms in the injured tissue. It is suggested that most pneumatosis cystoides intestinalis originates by contamination of the wall of the intestine through a mucosal injury, and that omental or wound gas-filled cysts occur only if the peritoneal cavity is contaminated in some manner. While these experiments do not disprove the theories advanced by others for the cause of this condition, it is believed the neoplastic theory is highly unlikely and that probably the neoplastic ulcer is the break in the mucosa that allows the bacteria (*C. perfringens*) to enter the injured tissue. The fact that intestinal pneumatosis cystoides intestinalis can occur after minimal injury and after i.p. monocontamination with this bacteria makes the biochemical, mechanical, and nutritional theories even less acceptable as possible alternative causes.

5733 GASTROINTESTINAL PROTEIN LOSS INDUCED BY ^{60}CO IRRADIATION OF THE ABDOMEN IN MICE.

(E.) Frankendal, B. (Dept. Gynecol. Radiat. Therapy, Univ. Umea, Sweden). *Acta Radiol.* [*Ther.*] *(Stockh.)*. 13(1):65-82, 1974.

The effect of different doses of irradiation, as judged by fecal activity, was investigated in 98 female NMRI mice. The extent to which the gastrointestinal protein loss varied with the size of the irradiation dose and with the interval after irradiation was considered. The source to skin distance was 35 cm and the absorbed dose rate was 860 ± 10 rad/min. The animals were irradiated with a total dose of 500, 1000, 2000, or 3000 rad given in daily fractions of 500 rad. Three days after the last irradiation a tracer, $^{51}CrCl_3$, was injected. Feces and urine were collected for 4 days. Since ^{51}Cr unites mainly with the plasma protein transferrin, this was taken as a measure of its leakage into the intestine. Abdominal irradiation was followed by increased loss of ^{51}Cr in the feces after irradiation with a total dose of 1000 rad in 2 equal fractions at a one day interval. Increasing the radiation dose did not produce any further increase in the loss of tracer in the feces. Mice irradiated with 1000 rad survived the 80 day observation period; thus this dose may be regarded as sublethal. These animals lost weight by 6 days after the end of irradiation but recovered their original weight within the following week. Seventy-five days after the end of irradiation, increased excretion of tracer in the feces was noted, suggesting that gastrointestinal changes may be irreversible.

5734 PAROXYSMAL NOCTURNAL HEMOGLOBINURIA ASSOCIATED WITH HEPATIC AND PORTAL VENOUS THROMBOSIS. *(E.)* Grossman, J. A.; McDermott, W. V., Jr. (Harvard Surg. Service, Boston City Hosp., Mass.). *Am. J. Surg.* 27(6):733-736, 1974.

Portal hypertension associated with other causes than hepatic cirrhosis is described in this report of 2 cases of an uncommon hematologic disorder, paroxysmal nocturnal hemoglobinuria, manifested by portal bed block. Mortality of 50% is associated with thrombotic phenomena of renal, mesenteric, cerebral, or peripheral vessels as well as portal vein occlusion. Also called Marchiafava-Micheli syndrome, this condition is a form of chronic hemolytic anemia characterized by hemoglobinuria, and is most prominent at night. The cause, at least in part, is an abnormality of the red blood cell membrane which increases its susceptibility to hemolysis in an acid medium and in the presence of serum complement. Patients seem to be particularly prone to infection. In one woman patient (55 yr old) polycystic hepatic and renal disease was present for 17 yr. Upon hospitalization, an inferior vena cavagram showed extrinsic pressure of the vena cava secondary to large hepatic cysts, and a hepatic venogram revealed complete occlusion of the main left hepatic vein. At postmortem, this vein was seen to be occluded by organized thrombus; a number of other major thrombi were evident including a partial, old one in the right main hepatic vein. Death precluded the development of a complete picture of portal hypertension; however, the early stages of portal bed block of the Budd-Chiari type were apparent. The 2nd patient, a 27 yr old woman in whom anemia was noted 10 years previously, was admitted to the hospital for anemia, hematemesis, and melena. Endoscopy showed that gastroesophageal varices were the source of hematemesis, while a celiac angiogram demonstrated splenic and proximal portal vein thrombosis. With a basic objective of decompression of varices and prevention of variceal hemorrhage, surgery included portal-azygos disconnection, splenectomy, and pyloroplasty, as well as anticoagulation treatment. The patient made an uncomplicated recovery. Since portal hypertension secondary to extrahepatic thrombotic occlusion may be more frequent than indicated by the scant literature, more information will be required to assess treatment, especially the effectiveness of the surgical approach used here.

GENERAL

Parasitology

5759 INTESTINAL PARASITE SURVEY OF KINDERGARTEN CHILDREN IN NEW ORLEANS *(E.)* Hubbard, D. W.; Morgan, P. M.; Yaeger, R. G.; Unglaub, W. G.; Hood, M. W.; Willis, R. A. (Tulane Univ. Sch. Pub. Health Trop. Med., New Orleans, La.). *Pediatr. Res.* 8(6):652-658, 1974.

A survey of intestinal helminths and protozoa was conducted in New Orleans public schools on 887 Negro kindergarten children (5 yr old) from whom 1 or more stool samples were collected. Of the sample population, 30.8% were infected with 1 or more species of intestinal parasites. One or more of the medically important species were found in 19.1%. The composite prevalence rates were as follows: *Ascaris* 2.3%; *Trichuris* 5.3%; *Enterobius* 2.6%; *H. diminuta* 0.1%; hookworm 0.1%; *Giardia* 10.6%; and *E. histolytica* 0.7%. Mixed infections of *Ascaris* and *Trichuris* occurred in 3 children; *Ascaris* and *Giardia* in 2; *Ascaris* and *E. histolytica* in 1; *Trichuris* and hookworm in 1; *Trichuris* and *Giardia* in 12; and *Giardia* and *E. histolytica* in 2. The percentages of medically unimportant species found in the survey were: *E. coli* 15.1%; *E. nana* 5.8%; *E. hartmanni* 0.3%; and *C. mesnili* 0.1%. Seven children had heavy or moderately heavy helminth infections: 2 with 200-250 eggs/smear, and 5 with 49-68 eggs/smear. Moderately heavy *Trichuris* infection with 14 eggs/smear was present in 1 child. None of the infected children demonstrated overt clinical signs or symptoms of parasitism. In general, the prevalence of intestinal parasites was high although the average intensity of infection was low. Since there are no long range plans to eradicate intestinal parasites in the United States, 4 practical control measures are listed for immediate and future handling of intestinal parasitism.

5760 ALTERED PARASITE DEVELOPMENT AND ENZYME LEVELS IN THE SMALL INTESTINE OF PARENTERALLY FED RATS. *(E.)* Castro, G. A.; Johnson, L. R.; Copeland, E.; Dudrick, S. J. (Univ. Texas Med. Sch., Houston). *Gastroenterology* 66(4):672, 1974.

GENERAL

Regional Enteritis

5761 EXCRETION OF CALCIUM AND CITRIC ACID IN PATIENTS WITH SMALL BOWEL DISEASE. *(E.)* Elliot, J. S.; Soles, W. P.; (VA Hosp., Palo Alto, Calif.). *J. Urol.* 111(6):810-812, 1974.

The 24-hr urinary excretion and concentration of oxalic acid, calcium, and citric acid were measured in a group of 10 male patients, aged 29-61 yr, with a variety of small bowel diseases. Hyperoxaluria was found in most patients, in those with a functioning colon and in those with an ileostomy and a nonfunctioning colon, suggesting that bacterial activity in the colon does not cause hyperoxaluria. Cultures of the ileal stoma showed few colonic bacteria, suggesting that bacterial colonization of the ileum is not a factor. Normal urinary oxalate and calcium in one patient with an absent colon and a normal small bowel indicated that a nonfunctioning colon and an ileostomy alone will not cause hyperoxaluria. Generally, the patients excreted small amounts of calcium and citric acid, with the reduction in citric acid excretion found in patients with idiopathic calcium oxalate stone disease. Although all urine specimens were supersaturated with calcium oxalate, the mean apparent solubility product for the group was significantly smaller than that of normal men or male idiopathic calcium oxalate stone patients. While hyperoxaluria undoubtedly contributes to supersaturation of the urine, the data suggest that something other than an increased oxalate excretion is responsible for the increased incidence of calcium oxalate stones. This other factor may be citric acid or an unknown substance.

5762 EARLY MANIFESTATIONS OF CROHN'S DISEASE IN ADOLESCENTS. *(E.)* Burbige, E. J.; Huang, S. S.; Bayless, T. M. (Dept. Med., Pediatr., Johns Hopkins Univ., Baltimore, Md.). *Gastroenterology* 66(4):669, 1974.
